

(12) United States Patent

Groeneweg

(54) DISTRIBUTED MAINTENANCE DECISION AND SUPPORT SYSTEM AND METHOD

(71) Applicant: Concaten, Inc., Golden, CO (US)

Inventor: Kevin K. Groeneweg, Golden, CO

Assignee: Concaten, Inc., Golden, CO (US)

Notice: Subject to any disclaimer, the term of this

patent is extended or adjusted under 35 U.S.C. 154(b) by 0 days.

This patent is subject to a terminal dis-

claimer.

Appl. No.: 16/015,008

Jun. 21, 2018 (22)Filed:

ABSTRACT

The present disclosure is directed to a computer that receives weather information from a weather service provider ("WSP") server and automatic vehicle locating system ("AVL") collected information from an AVL server, accesses a material performance specification for at least one treatment material, and determines, based on the weather information and/or AVL collected information and the material performance specification, a treatment recommendation for a selected roadway segment and/or route.

CROSS REFERENCE TO RELATED APPLICATION

The present application is a continuation of U.S. Ser. No. 15/180,474, filed Jun. 13, 2016 now U.S. Pat. No. 10,008, 112 issued Jun. 26, 2018, which is a continuation of U.S. application Ser. No. 14/556,240, filed Dec. 1, 2014 now U.S. Pat. No. 9,373,258 issued Jun. 21, 2016, which is a continuation of U.S. application Ser. No. 13/151,035 filed Jun. 1, 2011 now U.S. Pat. No. 8,902,081 issued Dec. 2, 2014 which claims the benefits of U.S. Provisional Application Ser. No. 61/350,802, filed Jun. 2, 2010, all entitled "Maintenance Decision Support System and Method", and which are incorporated herein by this reference in their entirety.

FIELD

The disclosure relates generally to maintenance vehicles and particularly to maintenance vehicles for controlling snow and ice accumulation on roadways.

BACKGROUND

To date, maintenance systems, such, as hose described by the U.S. Pat. No. 7,714,705, which is incorporated herein fully by this reference, have been based from a central server, which is ingesting both weather information received 30 from a weather service provider ("WSP"), such as the National Weather Service ("NWS") and, weather and maintenance information received from maintenance vehicles and remotely located sensors and sensor arrays, processing the ingested information, and attempting to provide recommendations to snow and ice maintenance vehicles in the field. The recommendations are commonly based on anticipated conditions and the last information the AVL server received from the vehicles and sensors and sensor arrays.

In one application, weather information is typically 40 ingested from the NWS and other sources into a central server controlled by a meteorological service provider (the meteorologist's central server or "MCS"). The weather information typically includes various reporting types ranging from data from weather stations to visual observations. 45 The MCS also ingests data from the field as last reported by maintenance vehicle operators and/or from assumptions within the system (e.g., one or more of the following: location, lane, weather condition, road condition, ambient and surface temperatures, blade and/or other vehicular or 50 engine information, wind directions and speeds, etc.). Data is typically processed by the MCS system on a periodic basis (e.g., every 1-20 minutes with some direct and indirect data being updated even less frequently). Meterologists and/or systems review the data and try to establish from the historic 55 record what has been done, predict what field operators should be seeing and expecting, and create forecasts and recommendations for what they should do, and then send applicable information back out to the field.

The system can have problems. For example, one problem 60 with the current system is that operators, when out of communication with the central server (e.g., out of cellular coverage area, unavailability of radio data channel, and the like) have no access or guidance. Other problems with these paradigms include without limitation: (1) the delay in 65 receiving and ingesting the weather and field information, (2) the delay in processing the same, (3) the delay in creating

2

forecasts and recommendations based on the same, (4) the delay in getting that information back out to the field, and (5) the delay in then responding to a change in variables if, for example, the operator reports the road is dry rather than wet (such as might be the case if the storm unexpectedly tracks south and/or with virgo). When in the latter case, the operator enters or reports dry roads from the field, the systems typically have to first qualify and then repeat the above process, sometimes with delays of 20 minutes or more. The delay can prevent effective control of snow and ice accumulation on roadways and cause extreme danger to motorists.

SUMMARY

These and other needs are addressed by the various aspects, embodiments, and/or configurations of the present disclosure. The disclosure is directed generally to treatment recommendations for maintenance vehicles, particularly 20 snow and ice maintenance vehicles.

In an embodiment, a method and distributed maintenance decision support system ("MDSS") are provided that include the operations:

- a) receiving, by an on-board computer in a selected 25 maintenance vehicle, one or more of weather information from a weather service provider ("WSP") server, automatic vehicle locating system ("AVL") collected information from an AVL server, and information collected locally by the on-board computer;
 - (b) accessing, by the on-board computer, a material performance specification for one or more treatment material(s) on-board the selected maintenance vehicle; and
 - (c) determining, based on the received information and the material performance specification, a treatment recommendation to be followed by the selected maintenance vehicle for a selected roadway segment and/or route.

In an embodiment, a method and distributed MDSS are provided that include the operations:

- (a) receiving, by a computer, weather information from a WSP server and AVL collected information from an AVL server:
- (b) accessing, by the computer, a material performance specification for one or more treatment material(s); and
- (c) determining, based on the weather information, AVL collected information, and the material performance specification, a treatment recommendation for a selected roadway segment and/or route.

The distributed maintenance system disclosed herein can obtain and locally process weather information, vendor information, collected historic AVL and/or other MDSS information, and/or sensor-based and visually collected information to determine and provide anti- and de-icing material treatment recommendations. The system can thus provide weather and/or other data points to the maintenance vehicles in the field, enable the maintenance vehicles to carry more relevant information, and, with such data and information, allow operators in, the maintenance vehicles, when needed and convenient, to input selected variables and then process and analyze, from their vehicles, the same immediately and directly in the field. This is directly contrary to central server-based maintenance systems, which ingest and process both weather and maintenance information to provide recommendations to the field. The distributed maintenance system can dramatically simplify, speed up, and improve the quality of in-vehicle support available to operators. In some configurations, the local processing is done in an on-board intelligent modem, such as an in-vehicle

SMD modem sold by IWAPI, Inc, (which integrates both full computing and modem functionality in the truck as further described U.S. Pat. No. 7,714,705). The intelligent modem can be particularly capable of this type of field functionality and of carrying and taking live feeds and/or updates of external data and information, presenting the same in processed and/or unprocessed form, and transmitting and/or storing data points, treatment recommendations and actual actions taken and interfacing with one or more central servers and/or systems (weather, accounting, maintenance or otherwise) for concurrent and/or subsequent review, analysis and reports.

In a configuration, the distributed MDSS takes a feed of basic weather and associated weather information directly 15 into the maintenance vehicle(s) (often without the feed first being processed by a server), where the operator can then use such data along with information from his own senses to enter actual (not guessed or historic) information into the on-board modem system to, for example but without limi- 20 tation, compute and receive a list of recommended de- or anti-icing materials to use, to evaluate and/or receive a treatment recommendation on the quantity of de- or antiicing material to put down, evaluate whether or to what extent the operator should delay treating or pre-treat a given 25 roadway, to graph and/or compare, such as visually, treatment material profiles (freeze characteristics at various temperature and dilution rates) to current and predicted temperatures, and the like.

In a configuration, the on-board modern downloads and/or 30 carries one or more de- or anti-icing material profiles for the de- or anti-icing materials most commonly used, with additional treatment material profiles or specifications being available via download as needed, as available, and/or as revised. Management and treatment material suppliers can 35 adjust treatment material specifications and/or profiles for characteristics, concentrations, and dilution rates, and/or other factors. Predicted storm start and stop times and other applicable weather information, such as predicted temperatures, wind speed, wind direction, solar thermal variable 40 (e.g., amount of sun and/or cloud cover which can be numerically represented on a selected numerical scale), are downloaded from the National Weather Service ("NWS") and/or other meteorological or weather service providers. Relevant data points may vary depending on the level of 45 service and/or sophistication desired. AVL collected information regarding which roads and/or segments have already been worked is downloaded from the same or other systems, with applicable time, treatment material and quantities used. The modem or similar in-vehicle computer device itself 50 collects (locally) information from various on-board sensors, including ambient and/or surface temperatures, humidity, and the like.

Operators (e.g., supervisors (by logging in remotely) and/or plow operators seeking an update and/or guidance on 55 recommended treatment materials and/or quantities, can at any time request an update, via a user interface (e.g., by touching a touch screen monitor (or otherwise—e.g., buttons, toggles, mouse cursor, keyboard, and voice commands)), input actual observed conditions (e.g., one or more 60 for ad condition, weather condition, snow on the road, estimated wind speed (if no sensor), drifting conditions, density of traffic, and/or other applicable factors) and quickly compare and/or recompute and/or display both the forecast conditions and the treatment recommendations 65 based on the applicable profiles, data, other information, and inputs recorded.

4

As disclosed in copending U.S. application Ser. No. 12/147,837, filed Jun. 27, 2008, now U.S. Pat. No. 8,275, 522, which is incorporated fully herein by this reference, radar (fixed and/or loop) can likewise be displayed directly from internal and/or third party systems (including without limitation NWS, internal meteorologists, and other weather service providers). As mentioned, relevant data points can vary depending on the level of service and/or sophistication the client desires in their application.

The display monitor can be used to toggle between applicable displays, and additional information can be pulled from files already on the system or specially downloaded from external systems located across the country or around the world. Visual and/or audible alerts can be provided.

Data points, treatment recommendations, and actual actions taken can be sent live, or via store-and-forward, to one or more central servers and/or systems (accounting, maintenance or otherwise) for concurrent and/or subsequent review, analysis and/or reports.

The source of weather information can be an accounting system, asset management, treatment materials management, or other processing and data system to/from which the in-vehicle units can transmit and receive. Processing, recommendations and general fleet management is normally still conducted from and/or through central systems, but the above process can enable operators in the field to much more quickly adjust parameters to the conditions they are encountering and obtain more timely, meaningful treatment recommendations and other information. Global Positioning System ("GPS")/Automated Vehicle Locating ("AVL") functionality is typically still provided with data, recommendations, actions, and/or other parameters recorded by location and time and collected for further review, analysis, and reporting requirements.

The distributed MDSS can also reduce or eliminate much of the expense and complexity of current meteorologist's central server or MCS where, from a given location, staff attempt to predict conditions at locations across the country and make recommendations that may or may not bear on actual fact. The distributed MDSS can combine human senses, with sensors and information that can be made available and processed in the vehicle efficiently, based on observed current conditions. It can eliminate an existing layer of unnecessary processing, delay and expense, and directly link and allow the maintenance vehicles to carry. compute, and/or display, even when out of coverage, information and treatment recommendations relevant to vehicle performance or other operation. It can enable clients to select and interchangeably choose weather service providers who most accurately meet their forecasting needs and/or save resources by drawing on the expertise and resources readily available internally and/or from the NWS and others.

These and other advantages will be apparent from the disclosure.

The phrases "at least one", "one or more", and "and/or" are open-ended expressions that are both conjunctive and disjunctive in operation. For example, each of the expressions "at least one of A, B and C" "at least one of A, B, or C", "one or more of A, B, and C", "one or more of A, B, or C" and "A, B, and/or C" means A alone, B alone, C alone, A and B together, A and C together, B and C together, or A, B and C together.

The term "a" or "an" entity refers to one or more of that entity. As such, the terms "a" (or "an"), "one or more" and "at least one" can be used interchangeably herein. It is also

to be noted that the terms "comprising", "including", and "having" can be used interchangeably.

The term "automatic" and variations thereof, as used herein, refers to any process or operation done without material human input when the process or operation is 5 performed. However, a process or operation can be automatic, even though performance of the process or operation uses material or immaterial human input, if the input is received before performance of the process or operation. Human input is deemed to be material if such input influences how the process or operation will be performed. Human input that consents to the performance of the process or operation is not deemed to be "material".

The term "computer-readable medium" as used herein 15 embodiment; refers to any tangible storage and/or transmission medium that participate in providing instructions to a processor for execution. Such a medium may take many forms, including but not limited to, non-volatile media, volatile media, and transmission media. Non-volatile media includes, for 20 example, NVRAM, or magnetic or optical disks. Volatile media includes dynamic memory, such as main memory. Common forms of computer-readable media include, for example, a floppy disk a flexible disk, hard disk, magnetic tape, or any other magnetic medium, magneto-optical 25 medium, a CD-ROM, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, a solid state reed urn like a memory card, any other memory chip or cartridge, a carrier wave as described 30 hereinafter or any other medium from which a computer can read. A digital file attachment to e-mail or other selfcontained information archive or set of archives is considered a distribution medium equivalent to a tangible storage medium. When the computer-readable media is configured 35 as a database, it is to be understood that the database may be any type of database, such as relational, hierarchical, objectoriented, and/or the like. Accordingly, the disclosure is considered to include a tangible storage medium or distribution medium and prior art-recognized equivalents and 40 successor media, in which the software implementations of the present disclosure are stored.

The terms "determine", "calculate" and "compute," and variations thereof, as used herein, are used interchangeably and include any type of methodology, process, mathematical 45 operation or technique.

The term "module" as used herein refers to any known or later developed hardware, software, firmware, artificial intelligence, fuzzy logic, or combination of hardware and software that is capable of performing the functionality 50 associated with that element. Also, while the disclosure is presented in terms of exemplary embodiments, it should be appreciated that individual aspects of the disclosure can be separately claimed.

The preceding is a simplified summary of the disclosure 55 to provide an understanding of some aspects of the disclosure. This many is neither an extensive nor exhaustive overview of the disclosure and its various aspects, embodiments, and/or configurations. It is intended neither to identify key or critical elements of the disclosure nor to delineate 60 the scope of the disclosure but to present selected concepts of the disclosure in a simplified form as an introduction to the more detailed description presented below. As will be appreciated, other aspects, embodiments, and/or configurations of the disclosure are possible utilizing, alone or in 65 combination, one or more of the features set forth above or described in detail below.

DETAILED DESCRIPTION

System Overview

In one embodiment, maintenance vehicles, such as trucks (e.g., snowplows), have on-board treatment material application algorithms and/or data structures to provide the operator with real-time or near real-time information regarding treatment material type, amount, concentration, and/or application rate to be applied to a roadway surface. The algorithms and/or data structures, for example, map a weather and/or traffic parameter (e.g., roadway surface temperature, wind speed and direction, solar thermal variable, precipitation level (e.g., snow depth, snow- or rain-fall rate, etc.), traffic volume, etc.) against one or more treatment material application parameters (e.g., treatment material type to be applied (e.g., sand, anti-icer, de-icer, etc.), treatment material performance specification or profile, treatment material amount, treatment material concentration, treatment material application rate, when and/or where to start application of the treatment material, and/or when and where to stop application of the treatment material). The algorithm may be two-, three-, four-, or more dimensional, depending on the application. An on-board computer, using the algorithm and operator input and/or sensor and/or other real-time input, determines a set of recommended treatment material application parameters. In one configuration, the algorithm maps roadway surface temperature against a treatment material application parameter. The parameters may be set manually by the operator and/or automatically by the computer. In one configuration, the operator input is road condition (e.g., road wet, dry, snow-packed, icy, etc.) In one configuration, the sensor input is ambient (external) temperature. In one configuration, the sensor input is loop radar from a Weather service provider (such as the National Weather Service). In one configuration, the input is a set of predicted weather conditions from a weather service pro-

In one embodiment, a maintenance vehicle, particularly a truck (e.g., a snowplow or other vehicle type), receives, from a weather service provider, loop radar, satellite image(s), and other weather forecast information and, from an operator and/or on-board sensor, sensed or collected information, such as road/track condition (e.g., dry, wet, snow-packed,

etc.) outside ambient temperature, dew point, weather condition (e.g., raining, snowing, sunny, cloudy, etc.), traffic volume or level etc. An on-board computer uses the input to determine, using stored algorithms and/or data structures such as those discussed above, recommended treatment 5 material application parameters. The input received from the on-board sensor(s) and/or operator and/or treatment recommendations can be provided to a central server, such as a server of a weather service provider and/or other system, to refine a weather prediction model, dispatch or maintenance 10 system, and/or road mapping or profiling module.

In one embodiment, a supervisor can receive weather information, automatic vehicle locating ("AVL") system collected information, and locally collected information and, remote from the AVL server, determine treatment recommendations on a maintenance vehicle-by-maintenance vehicle basis.

The Distributed Data Processing Network

An embodiment of the distributed maintenance system will now be discussed with reference to FIG. 1.

The system 100 includes, without limitation, a plurality of maintenance vehicles 104*a-n* operated by operators, a computer device 108 operated by a supervisor, dispatcher, or other non-operator, a weather service provider 112 an automatic vehicle locating ("AVL") system 116, and a vendor 25 120, all interconnected by a network cloud 124.

The maintenance vehicles **104***a-n* can be any type of maintenance vehicle and is typically operated by a governmental entity, such as a state, city, county, municipality, and the like or by a contractor to a governmental entity. An 30 exemplary maintenance vehicle **104***a-n* is a snow and/or ice removal vehicle, such as a snow plow.

The computer device 108 can be any type of computer, including, without limitation, a laptop, personal computer, intelligent cellular phone, personal digital assistant, and the 35 like.

The weather service provider 112 is a private or governmental entity that provides weather information. Examples of weather service providers include the National Weather Service ("NWS"), University Corporation for Atmospheric 40 Research ("UCAR") National Center for Atmospheric Research ("NCAR"), Meridian Environmental Technology Inc. ("Meridian"), Vaisala Inc. ("Vaisala"), and Televent GIT S.A. ("Televent").

"Weather information" refers to any information describing the state of the atmosphere at a particular time and place. Weather information includes, without limitation, current and/or future (predicted or forecasted) air temperature, solar thermal variable (e.g., sunny, cloudy, partially cloudy, visibility measure, sky condition, etc.), precipitation type (of 50 whatever form, whether rain, snow, hail, ice, or combination thereof), precipitation rate, and/or precipitation amount, relative humidity, dew point, wind speed, wind direction, wind chill, pressure (altimeter), and barometric pressure.

Weather information can be presented in many forms, 55 including, without limitation, as an associated value (measured relative to a determined scale, index, or rating) and optionally probability of occurrence or as a weather map or graphical weather information (e.g., visible and/or infrared satellite image, fixed or loop radar image (e.g., manually 60 digitized radar, radar coded messages, or NEXTRAD data), NAM model forecast, surface data, upper air data, GFS model forecast, WRF model forecast, rapid update cycle ("RUC") forecast model, and European Center for Medium range Weather Forecasting (ECMWF) forecast model). The 65 weather map may be refreshed after a determined period, such as a Doppler loop radar feed. The forecast may be for

8

a specified time period, such as 1-hour, 4-hour, 6-hour, 8-hour, 12-hour, 18-hour, 24-hour, 48-hour, 72-hour, 10-day, and the like.

The AVL system 116 uses a satellite locating and positioning system, such as the Global Positioning System ("GPS"), to track, automatically, current and historic maintenance vehicle 104a-n locations, maintenance vehicle 104a-n current and historic state, maintenance vehicle current and anticipated dispatch information, and maintenance vehicle current and historic activities (hereinafter referenced as "AVL collected information. "Vehicle state" refers to a condition, function, location, or operation of a vehicle or a component or accessory thereof. In one configuration, the historic information is collected by on-board modems. The information can include vehicle speed, vehicle acceleration, engine revolutions-per-minute, engine temperature, engine oil pressure, fuel level, battery amperage, battery voltage, odometer setting, tire pressure, mileage per gallon, other onboard warning systems and sensors, weather conditions (such as temperature, humidity, wind speed and direction, wind chill, raining, snowing, blowing snow, foggy, clear, overcast, etc.), road conditions (e.g., icy, slushy, snowpacked, frosty, wet, dry, etc.), physical location (e.g., GPSbased location), snow plow setting (e.g., snowplow position and orientation such as plow up or down and angle relative to the truck longitudinal axis), mixture, application rate, and amount of a treatment material (e.g., an abrasive and/or deor anti-icing material) applied to a selected roadway surface (e.g., salt level, sand level, magnesium sulfate level, other chemicals or treatment materials, and combinations thereof), when (e.g., timestamp) the treatment material was last applied to the selected roadway surface, video images of the vehicle's exterior environment or the vehicles' interior or exterior, audio of the vehicle's interior, radiation levels, roadway friction measures (one of ordinary skill in the art will readily appreciate that there are many sensors available in the marketplace to sense roadway friction, or lack thereof caused by the accumulation of ice, and that these sensors can be mounted on the maintenance vehicle and thereby collect roadway friction data in real-time as the maintenance vehicles traverses a given route), thermal and/or infrared imaging, traffic level (which can be quantified on a numerical scale), solar energy level (which can be quantified on a numerical scale), earliest dispatch time of next available snow maintenance vehicle to treat selected roadway, and other information which can be displayed, sensed and/or input, manually (typically visually by the operator) or on an automated basis.

The vendor 120 is a provider of one or more treatment materials on-board a selected maintenance vehicle. The vendor 120 can provide treatment material performance specifications, particularly profiles of the type depicted in FIG. 3. The treatment material performance specifications an be of any form that is processable by a computer processor.

The network 124 can be wired, wireless, or a combination thereof. In one configuration the network 124 is a wireless network. The wireless network can be any type of wireless service and/or air interface, including, without limitation, time-, frequency-, and code-division multiple access, and combinations thereof such as orthogonal frequency-division multiple access. Examples include WIMAX, LTE, Advanced Mobile Telephone Service or AMPS, Digital Advanced Mobile Telephone Service or D-AMPS, Digital Communication Service or DCS1800, Global System for Mobile Communications/General Packet Radio Service or GSM/GPSR, North American Digital Cellular, Personal

Communications Services, Personal Digital Cellular, Total Access Communication System, High Speed Downlink Packet Access or HSDPA, Enhanced Data GSM Environment or EDGE, 1×RTT CDMA, CDMA2000, Evolution Data Optimized or EVDO, Digital Enhanced Network or 5 iDEN, Specialized Mobile Radio or SMR, 802.11x, WiMAX or 802.16, and other public and private networks, with Frequency Division Multiple Access or FDMA, Time Division Multiple Access or TDMA, Code Division Multiple Access or COMA, Cellular Digital Packet Data or 10 CDPD, Wideband CDMA or WCDMA/UMTS, or others. The public or private network 124 can be either landline or wireless. Wireless networks can be operated by one or more private or public networks, including carriers, such as SprintTM, VerizonTM, CingularTM, AlltelTM, Western Wire- 15 less™, AT&T Wireless™, Unicell™, Westlink™ and others, as well as affiliates thereof. Bandwidth and/or transmission speeds, and/or the frequency and method of data transmissions, may be intentionally limited (by setting appropriate modem parameters) to qualify for favorable telemetry rates. 20 of operation

Each of the maintenance vehicles 104a-n and computer device 108 includes a maintenance decision module 128. The maintenance decision module 128 will be described with reference to FIG. 2. The modem 200 may be provided with a memory 204 including a number of internal logic 25 modules and other information for performing various operations. The memory 204 includes AVL collected information 208, treatment material performance specifications 212 (which may be in multiple forms for a selected treatment material and/or in the same form but for multiple treatment 30 materials) that correspond to a treatment material on-board a selected maintenance vehicle, locally collected information 216, which refers to AVL-type information collected by a selected maintenance vehicle and stored locally, weather information 220, a system clock 224 that is synchronized to 35 a universal time clock and provides internal timing information to control modem 200 operations and timestamp collected data, a unique identifier 228 which is different from a network address associated with the modem 200 (which thereby provides unique identification should the 40 network address be non-static (or dynamically changing)), a map 232 which can take many forms, including without limitation one or more of the forms described in U.S. Pat. No. 7,714,705 and copending U.S. application Ser. No. 12/147,837 (in which the map provides satellite and/or radar 45 weather information), operator instructions 236 received from the operator of the selected maintenance vehicle. vehicle physical location 240 (which typically is a set of spatial coordinates from the electrically connected satellite positioning module 908), and the maintenance decision 50 module 128. The modem 200 is further connected to or integrated with one or more of the satellite positioning module 908, antenna 906, on-board sensors 252, video imaging device 256, user interface 260, and wireless network access card 264. Sensors 252 can be any device for 55 collecting weather and/or AVL collected information 220 and 208, including, without limitation, surface and air temperature sensors. The memory 204 is used during normal data processing operations and as a buffer for data collected when the connection with the network is either unhealthy or 60

FIG. 4 depicts a snow maintenance vehicle, particularly a snow plow, according to an embodiment. The vehicle 1500 includes a snow plow 1504, an antenna 906 for duplexed communications, satellite positioning module 908 and a 65 corresponding antenna 912, a roadway surface temperature sensor 916, and spreader 1508 connected to a treatment

10

material container positioned in the bed of the snow maintenance vehicle. Although the characteristics (e.g., concentration and types) of the treatment materials on-board the vehicle 1500 are selected before deployment, it is possible that various types of treatment materials (such as one or more treatment materials and water) are contained in separate vessels or containers on the vehicle 1500 and mixed during deployment to provide desired treatment material characteristics. The specific treatment material(s) and corresponding characteristic(s) on board the vehicle 1500 can be entered into the memory 204 by the operator, supervisor, or other personnel, via a user interface or captured automatically by the maintenance decision module 128, such as by radio frequency identification techniques (with an active or passive tag on the vessel or container and a fixed or mobile reader on the vehicle 1500 and in communication with the modem 200). Other automated identification techniques may be employed, such as bar codes.

The maintenance decision module **128** performs a number of operation

In one set of operations, it oversees operations of the modem 200, identifies the types of digital incoming signals (e.g., by sensor type) and, based on the type of incoming signal, translates the digital signals received from the sensors to a selected language or format, packetizes the collected data 216 with a data-type identifier included in the payload and applies headers to the packets for uploading onto the network, handles mail and messaging functions, includes drivers and programming for the user interface, performs remote system maintenance and troubleshooting functions, and other functions.

In another set of operations, the maintenance decision module 128 processes and analyzes one or more of AVL collected information 208 (such as when a selected roadway segment was last treated, how it was treated, the amount of treatment material applied to the selected roadway segment, visually observed roadway condition of the selected roadway segment, visually observed traffic level on the selected roadway segment, visually observed precipitation type, rate, and/or accumulation), treatment material performance specifications 212, locally collected information 216 (such as how a selected roadway segment is currently being treated by the maintenance vehicle associated with the maintenance decision module 128. the amount of treatment material currently being applied to the selected roadway segment by the associated maintenance vehicle, current operator observed roadway condition of the selected roadway segment, current operator observed traffic level on the selected roadway segment, current operator observed precipitation type, rate, and/or accumulation), operator instructions 236, and weather information 220 to provide treatment recommendations, which may be specific to a specific location, route, roadway, etc., and responsive to one or more lane treatment efforts to a local operator, a local or remote supervisor, and/or the AVL system 116 server and/or to automatically control on-board maintenance vehicle treatment operations consistent with the treatment recommendations. The treatment recommendations include, for example, a treatment material type (e.g., abrasive and/or de- or anti-icing material), treatment material application amount (e.g., pounds of treatment material per lane-mile), treatment material application rate (e.g., amount of treatment material per unit time), concentration of de- or anti-icing agent (e.g., amount of agent per unit volume of liquid solution), treatment material mixture composition (types of de- or antiicing agents to be included in the composition), plowing strategy, pre-storm treatment strategy (which can include ·

any of the prior elements), mid-storm treatment strategy (which can include any of the prior elements), post-storm treatment, strategy (which can include any of the prior elements), a treatment location, and the like.

11

The treatment recommendations can be based on actual 5 and/or predicted information, hypothetical information, or a combination thereof. The maintenance decision module 128 typically has a data ingest submodule to receive and universally format the various types of information, a road weather forecast submodule to dynamically weight one or 10 more forecast models and forward error correction with observations, and a road condition and treatment submodule that, based on the output of the data ingest and road weather forecast submodules, forecasts road temperature and condition and maps the forecasts to a look up table of rules of 15 practice for anti-icing and/or de-icing and/or plowing operations to provide treatment recommendations. The rules of practice commonly use treatment material performance specifications, such as eutectic curves, for differing types of treatment materials and dilution information. In one con- 20 figuration, the maintenance decision module 128 uses known, developed or proprietary maintenance decision support system ("MDSS") algorithms, as may be provided by UCAR, NCAR, Vaisala, Televent, Meridian or others, the latter of which might for example include the MDSS ProTM 25 product from Meridian, modified for use in a maintenance vehicle to provide treatment recommendations. MDSS ProTM uses a pavement model, which considers the interaction of a treatment material with weather, traffic, and other factors. In one configuration, the maintenance decision 30 module 128 uses an algorithm capable of having as inputs not only weather information and AVL collected information but also maintenance vehicle operator and/or supervisor observations, such as traffic level, solar energy level, wind speed and direction, dilution, road (e.g. surface, grade, 35 slope, and crown) and/or other factors. In one configuration the maintenance decision module 128 uses any of the above algorithms along with a roadway profiling model that characterizes or defines selected segments of roadways associated with specific satellite location coordinates. The profil- 40 ing model can include factors influencing the concentration or effectiveness of the treatment material as a function of time, including, without limitation, the tendency or potential of the selected roadway segment to accumulate snow drifts for differing wind directions, the longitudinal grade of the 45 selected roadway segment (which affects the runoff quantity and/or rate), the transverse slope and crown of the selected roadway segment (which affects the runoff quantity and/or rate), the roadway surface temperature behavior (e.g., bridges commonly have lower roadway surface tempera- 50 tures than roadway surfaces having a subsurface road bed), the tendency of the selected roadway surface to receive sunlight throughout the day (e.g., whether the selected roadway surface is fully shaded throughout the day, partially shaded throughout the day, or unshaded), the type and 55 condition of the pavement, if any, on the selected roadway surface, and the like.

The treatment material can be a dry or wet abrasive solid particulate, such as sand or gravel, or a dry or wet de- or anti-icing agent, such as brine and other salt-containing 60 liquid or solid solutions. Exemplary de- or anti-icing agents include magnesium chloride (MgCl.sub.2), sodium chloride (NaCl), potassium chloride (KCl), calcium chloride (CaCl.sub.2), calcium magnesium acetate (CMA) (a combination of CaCO.sub.3, MgCO.sub.3, and acetic acid 65 (CH.sub.3COOH)), potassium acetate (KAc) (CH.sub.3COOK), CMS-BTM or MotechTM, CG-90 Surface

12

SaverTM, VerglimitTM, ethylene glycol (or ethane-1,2 diol), urea (NH.sub.2CONH.sub.2), and methanol (CH.sub.3OH), to name but a few. The treatment material can be sprayed directly onto a roadway or onto an abrasive solid particulate, which is then applied to a roadway. The treatment material can be applied to the roadway before, during, and/or after a precipitation event.

Prior to discussing examples illustrating the operation of the maintenance decision module 128, treatment material performance specifications or profiles will be explained. Referring to FIG. 3, a phase diagram for various de- and/or anti-icing agents is provided. One of ordinary skill in the art will readily appreciate that the addition of a de-icing or anti-icing agent, commonly in the form of a salt, to water will decrease the temperature at which the water freezes. This is known a depressing the freezing point. For example, and referring now to FIG. 3, Potassium acetate (KAc) at a concentration of 50% by weight has the highest water freezing point depression. This concentration of potassium acetate will depress the freezing point of water from 32.degree. F to -80.degree. F. On the other hand, sodium chloride (NaCl) at a concentration of 23% by weight has the lowest water freezing point depression, depressing the freezing point from 32.degree. F to -5.degree. F. As precipitation falls or evaporates and/or as traffic moves a treatment material off the roadway, the effective concentration of the treatment material will change, causing a change in the effective freezing point depression. As concentration decreases, the effective freezing point depression will decrease, and, as concentration increases, the effective freezing point depression will increase. At periodic intervals, the treatment material will need to be reapplied to the roadway surface to control ice formation. For example, at time T.sub.1, the concentration of calcium chloride on a selected roadway surface is 24% by weight and freezing point depression is about -20.degree. F., and, at later time T.sub.2, the calcium chloride concentration on the selected roadway surface has decreased, as a result of traffic and continued precipitation, to 9% by weight and the freezing point depression is about 21.degree. F. At time T.sub.1, the selected roadway surface has a temperature of 5.degree. F. and, at time T.sub.2 due to a drop in the ambient air temperature, of about 0.degree. F. As will be appreciated, surface prediction modeling software is available to characterize the thermal response of surface temperature to various factors including ambient air temperature. Although the calcium chloride will prevent ice formation at time T.sub.1, it will not have a significant retardant effect on ice formation at time T.sub.2, unless the treatment material is reapplied to the selected roadway surface. As will be appreciated, the ability to predict successfully the effect of precipitation (through snow- or rainfall, and wind speed and direction (which will cause drifting)) and traffic on treatment material concentration on the roadway surface and the impact of air temperature and solar energy (from sunlight) on surface temperature can be important to controlling effectively application and re-application of treatment material and therefore ice formation.

In a first operational example, a snow plow has sodium chloride and sand on board and is applying both treatment materials to a roadway during a snow storm. The snow storm currently (at 6 am on Monday) has a precipitation rate of about 1 inch of snow accumulation per hour, a surface temperature is about 30.degree. F., an ambient air temperature is about 20.degree. F., a wind speed of 15 mph, a wind direction of westerly, and solar thermal variable is low. The snow storm 6-hour forecast is a continuing (average) pre-

cipitation rate of about 1 inch of snow accumulation per hour, the surface temperature will drop to about 25.degree. F., the ambient air temperature will rise to about 25.degree. F. (maximum), the wind speed will remain constant at about 15 mph with no change in wind direction, and solar thermal 5 variable will remain low. This information is provided to the modem 200 by the weather service provider 112 server. The AVL system 116 server further provides to the modem 200 collected information indicating that a selected section of roadway was last treated with a 10% by weight liquid 10 sodium chloride at 3 am. The modem 200 further knows by RFID techniques that the on board sodium chloride has a concentration of 15% by weight. The snow plow operator further inputs into the modem that traffic is currently light but will increase to a high level from 7 am to 9 am as rush 15 hour approaches. In response to these factors, the maintenance decision module 128 recommends to the driver that he apply both sand and sodium chloride, with a sodium chloride application rate of 100 gallons per lane mile. This will substantially inhibit ice formation during rush hour. The 20 module 128 further recommends that the sodium chloride be reapplied no later than 10 am.

Another operational example uses the information set fog in the prior example with the exception that the storm is predicted to stop at 10 am followed by a cloudless sky at 11 25 am. Using this information, the maintenance decision module 128 recommends that no further treatment material be applied after the current maintenance vehicle. The solar energy from the sun will increase surface temperature and melt the snow on the roadway in the absence of additional 30 treatment material.

In another operational example, a supervisor, via a laptop computer containing maintenance decision module 128 and connected remotely, over a public and/or untrusted network, to modems 200 and the AVL server, is able to determine, for a set of satellite position coordinates, a set of treatment recommendations to be used by snow maintenance vehicles under his supervision. The supervisor is able to access, for a selected set of satellite position coordinates, weather information 220 from a weather service provider 112 server, and treatment material performance specifications 212 from a vendor 120, and locally collected information 216 from a selected snow maintenance vehicle. The supervisor may not be himself operating a maintenance vehicle.

The information can be easily accessed by the supervisor using the map display of FIG. 5. As can be seen from FIG. 5, the spatial map 1400 shows vehicle locations, vehicle operations, and other state information. For example, the map 1400 can depict the location of each of a number of 50 snowplow trucks 1500 (FIG. 4) using an icon 1404a-d denoting each truck. The icon 1404 color can be varied to indicate differing vehicle states. Text information 1408a-d can be depicted on the map adjacent to or associated with each icon 1404. The text information 1408 can describe 55 selected state information associated with the truck 1500, such as a truck identifier 1412, direction of travel 1416, speed 1420, status of GPS signal 1424, and timestamp 1428 of last data update for the identified truck. The map 1400 can also depict, for a selected vehicle, a trace route over a 60 selected period of time. By selecting a particular truck icon 1404, the supervisor is able to view not only the particular information collected by the AVL system 116 from the truck but also a live video feed of the roadway (via the video imaging device 256). Although not depicted, the map can 65 include one or more sensor icons depicting a stationary meteorological sensor, pavement sensor, roadway cam, and/

14

or weather cam and, by selecting the sensor icon, view the associated media or multimedia information being collected.

The map can further include a tool bar 500 including a series of user selectable options. The options include use currently sensed satellite position 504, select new sensed satellite position 508 (which is done by selecting the option and selecting, on the map, from a drop-down list, or otherwise, a desired map location), use collected information for current satellite position 512 (the collected information refers to the weather information 220, AVL collected information 208 and locally collected information 216), edit collected information 520 (which permits the user to edit the collected information to determine treatment recommendations for a "what-if" or hypothetical scenario for the current satellite position), view weather information for current satellite position 524, view AVL collected information for current satellite position 528, view current treatment recommendations for the current satellite position 532, determine treatment recommendations 536 (using unedited or edited information), and edit treatment recommendations 540.

Using these options, the supervisor can select a satellite position, view various types of past, current, and future information (including the information discussed above), edit the information, and determine treatment recommendations. The treatment recommendations can be determined not only for the unedited information but also for edited information. In this manner, the supervisor can determine different treatment recommendations for different scenarios and customize the treatment recommendations for the current satellite position. The supervisor further has the ability to edit the treatment recommendations before transmittal. This information can be forwarded directly to a selected maintenance vehicle or indirectly to the selected maintenance vehicle via the AVL system 116 server. As will be appreciated, a maintenance vehicle operator can use the same features and perform the same maintenance decision module activities as the supervisor.

While the various components in FIG. 2 have been described with reference to a modem, it is to be understood that one or more of the components may also be connected to or stored in the computer device 108.

Operation of the Maintenance Decision Module

With reference to FIGS. 6-7, a first operational embodiment will be discussed.

In step 600 the maintenance decision module 128 detects a stimulus. Exemplary stimuli include time value, operator or user input, or a change in monitored parameters such as ambient or surface temperature, location, or traction.

In step 604, the maintenance decision module 128, in response to the detected stimulus, requests 700 updated weather information 220 from the weather service provider 112 server.

In step 608, the maintenance decision module 128 requests 704 updated AVL collected information 208 from the AVL 116 server.

In optional step 612, the maintenance decision module 128 requests 708 material performance specifications 212 from the vendor 120 server.

The weather service provider, AVL, and vendor servers provide responses **712**, **716**, and **728**, respectively.

In step 616, the maintenance decision module 128 determines treatment recommendations based on the information.

In step 620, the maintenance decision module 128 provides treatment recommendations and locally collected information to a decision maker. The decision maker may be the maintenance vehicle operator, a supervisor, a dispatcher, the AVL server, or a combination thereof.

In step 624, the maintenance decision module 128 receives input from the decision maker. The input may be edits to the treatment recommendations, locally collected information, weather information, material performance specifications, AVL collected information, or a combination thereof. When requested, the maintenance decision module returns 632 to step 604 and repeats the foregoing steps. The optional provision of the treatment recommendations to the AVL server and the response therefrom are shown by signals 724 and 728, respectively. The input may also be an indication that the treatment recommendation is accepted and will be, is being, or has been performed.

In step 628, the maintenance decision module 128 reports 732 the action taken to the AVL 116 server.

With reference to FIGS. 8-9, a second operational embodiment will be discussed.

In step 600, the maintenance decision module 128 detects a stimulus.

In step 800, the maintenance decision module 128, in $_{20}$ response to the detected stimulus, requests 900 updated selected information from the AVL server.

In step 804, the AVL server, in response, requests 904 weather information 220 from the weather service provider 112 server

In optional step 808, the maintenance decision module 128 requests 910 material performance specifications 212 from the vendor 120 server.

The weather service provider and vendor servers provide responses 912 and 916, respectively.

In step 812, the AVL server provides 920 the selected information to the maintenance decision module 128.

In step 816, the maintenance decision module 128 determines treatment recommendations based on the information.

In step **820** the maintenance decision module **128** pro- 35 vides treatment recommendations and locally collected information to a decision maker. The decision maker may be the maintenance vehicle operator, a supervisor, a dispatcher, the AVL server, or a combination thereof.

In step 824 the maintenance decision module 128 receives 40 input from the decision maker. The input may be edits to the treatment recommendations, locally collected information, weather information, material performance specifications, AVL collected information, or a combination thereof. When requested, the maintenance decision module returns 832 to 45 step 804 and repeats the foregoing steps. The optional provision of the treatment recommendations to the AVL server and the response therefrom are shown by signals 924 and 928, respectively. The input may also be an indication that the treatment recommendation is accepted and will be, 50 is being, or has been performed.

In step 828, the maintenance decision module 128 reports 932 the action taken to the AVL 116 server.

In the above operational examples, the modem 200 commonly accesses information from servers by directing the 55 information request to a specified universal resource indicator ("URI") or locator ("URL") associated with a selected server. In other words the modem 200 pulls the desired information from the server as opposed to the server pushing the desired information to the modem 200. In one configuration, the modem 200 accesses the desired information from a web page associated with the URI or URL. This is done due to dynamically changing network (typically Internet Protocol ("IP")) addresses for the modem. When static IP addresses are associated with the modems, the server can push the desired information to the static IP address of the selected modem.

16

The information is typically converted into a selected form, packetized, and transmitted over the wireless network. The form of the information can be in accordance with any selected language, such as the eXtensible Markup Language or XML, the HyperText Markup Language or HTML, Remote Method Invocation or RMI, or Direct Socket Connections. The packets can be transported using any suitable protocol, such as the Transport Control Protocol/Internet Protocol suite of protocols, Simple Object Access Protocol, or User Datagram Protocol.

The connection may be terminated involuntarily or voluntarily by the modem 200 in response to a set of predetermined trigger events. One trigger event is a command by the user. Another trigger is when the received signal strength from the network falls below a selected threshold. Signal strength may be measured using the mechanisms currently used by cell phones to measure and report the signal strength to the user, even though the user has not yet placed a call. Yet another trigger is one or more selected quality of service (QoS) parameters falling below a corresponding predetermined threshold. Exemplary QoS parameters include packet loss, jitter, latency, etc. Notwithstanding the loss of connection, the maintenance decision module 128 may continue operation and determine treatment recommendations during connectivity loss.

Data collection by the modem may be periodic or continuous. Periodic data collection may be based on one or more trigger events, such as the passage of a selected time interval, passage of a given number of data entries (either in total or sorted by parameter), detection of a change in one or more selected state parameters or variables, or receipt of a data transmission command by a user. When collected data is to be transmitted and the connection is either down or up but unhealthy, the modem buffers the data in the memory 204 while the monitor attempts to reestablish the connection with the same or a different network. When the connection is reestablished, the data is transmitted via the network to the remote server.

A number of variations and modifications of the invention can be used. It would be possible to provide for some features of the invention without providing others.

In yet another embodiment, the systems and methods of this disclosure can be implemented in conjunction with a special purpose computer, a programmed microprocessor or microcontroller and peripheral integrated circuit element(s), an ASIC or other integrated circuit, a digital signal processor, a hard-wired electronic or logic circuit such as discrete element circuit, a programmable logic device or gate array such as PLD, PLA, FPGA, PAL, special purpose computer, any comparable means, or the like. In general, any device(s) or means capable of implementing the methodology illustrated herein can be used to implement the various aspects of this disclosure. Exemplary hardware that can be used for the disclosed embodiments, configurations and aspects includes computers, handheld devices, telephones (e.g., cellular, Internet enabled, digital, analog, hybrids, and others), and other hardware known in the art. Some of these devices include processors (e.g., a single or multiple microprocessors), memory, nonvolatile storage, input devices, and output devices. Furthermore, alternative software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the methods described herein.

In yet another embodiment, the disclosed methods may be readily implemented in conjunction with software using object or object-oriented software development environ-

ments that provide portable source code that can be used on a variety of computer or workstation platforms. Alternatively, the disclosed system may be implemented partially or fully in hardware using standard logic circuits or VLSI design. Whether software or hardware is used to implement the systems in accordance with this disclosure is dependent on the speed and/or efficiency requirements of the system, the particular function, and the particular software or hardware systems or microprocessor or microcomputer systems being utilized.

In yet another embodiment, the disclosed methods may be partially implemented in software that can be stored on a storage medium, executed on programmed general-purpose computer with the cooperation of a controller and memory, a special purpose computer, a microprocessor, or the like. In these instances, the systems and methods of this disclosure can be implemented as program embedded on personal computer such as an applet, JAVA® or CGI script, as a resource residing on a server or computer workstation, as a routine embedded in a dedicated measurement system, system component, or the like. The system can also be implemented by physically incorporating the system and/or method into a software and/or hardware system.

The exemplary systems and methods of this disclosure 25 have been described in relation to a distributed processing network. However, to avoid unnecessarily obscuring the present disclosure, the preceding description omits a number of known structures and devices. This omission is not to be construed as a limitation of the scopes of the claims. Specific 30 details are set forth to provide an understanding of the present disclosure. It should however be appreciated that the present disclosure may be practiced in a variety of ways beyond the specific detail set forth herein.

Furthermore, while the exemplary aspects, embodiments, 35 and/or configurations illustrated herein show the various components of the system collocated, certain components of the system can be located remotely, at distant portions of a distributed network, such as a LAN and/or the Internet, or within a dedicated system. Thus, it should be appreciated, 40 that the components of the system can be combined in to one or more devices, such as a modem, or collocated on a particular node of a distributed network, such as an analog and/or digital telecommunications network, a packet-switch network, or a circuit-switched network. It will be appreci- 45 ated from the preceding description, and for reasons of computational efficiency, that the components of the system can be arranged at any location within a distributed network of components without affecting the operation of the system. For example, the various components can be located in one 50 or more communications devices, at one or more users' premises, or some combination thereof. Similarly, one or more functional portions of the system could be distributed between a telecommunications device(s) and an associated computing device.

Furthermore, it should be appreciated that the various links connecting the elements can be wired or wireless links, or any combination thereof, or any other known or later developed element(s) that is capable of supplying and/or communicating data to and from the connected elements. 60 These wired or wireless links can also be secure links and may, be capable of communicating, encrypted information. Transmission media used as links, for example, can be any suitable carrier for electrical signals, including coaxial cables, copper wire and fiber optics and may take the form 65 of acoustic or sight waves, such as those generated during radio-wave and infra-red data communications.

18

Also, while the flowcharts have been discussed and illustrated in relation to a particular sequence of events, it should be appreciated that changes, additions, and omissions to this sequence can occur without materially affecting the operation of the disclosed embodiments, configuration, and aspects.

Although the present disclosure describes components and, functions implemented in the aspects, embodiments, and/or configurations with reference to particular standards and protocols, the aspects, embodiments, and/or configurations are not limited to such standards and protocols. Other similar standards and protocols not mentioned herein are in existence and are considered to be included in the present disclosure. Moreover, the standards and protocols mentioned herein and other similar standards and protocols not mentioned herein are periodically superseded by faster or more effective equivalents having essentially the same functions. Such replacement standards and protocols having the same functions are considered equivalents included in the present disclosure.

The present disclosure, in various aspects, embodiments, and/or configurations, includes components, methods, processes, systems and/or apparatus substantially as depicted and described herein, including various aspects, embodiments, configurations embodiments, subcombinations, and/ or subsets thereof. Those of skill in the art will understand how to make and use the disclosed aspects, embodiments, and/or configurations after understanding the present disclosure. The present disclosure, in various aspects, embodiments, and/or configurations, includes providing devices and processes in the absence of items not depicted and/or described herein or in various aspects, embodiments, and/or configurations hereof, including in the absence of such items as may have been used in previous devices or processes, e.g., for improving performance, achieving ease and/or reducing cost of implementation.

The foregoing discussion has been presented for purposes of illustration and description. The foregoing is not intended to limit the disclosure to the form or forms disclosed herein. In the foregoing Detailed Description for example, various features of the disclosure are grouped together in one or more aspects, embodiments, and/or configurations for the purpose of streamlining the disclosure. The features of the aspects, embodiments, and/or configurations of the disclosure may be combined in alternate aspects, embodiments, and/or configurations other than those discussed above. This method of disclosure is not to be interpreted as reflecting an intention that the claims require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive aspects lie in less than all features of a single foregoing disclosed aspect, embodiment, and/or configuration. Thus, the following claims are hereby incorporated into this Detailed Description, with each claim standing on its own as a separate preferred embodiment of the disclosure.

Moreover, though the description has included description of one or more aspects, embodiments, and/or configurations and certain variations and modifications other variations, combinations, and modifications are within the scope of the disclosure, e.g., as may be within the skill and knowledge of those in the art, after understanding the present disclosure. It is intended to obtain rights which include alternative aspects, embodiments, and/or configurations to the extent permitted, including alternate, interchangeable and/or equivalent structures, functions, ranges or steps to those claimed, whether or not such alternate, interchangeable and/or equivalent structures, functions, ranges or

19

steps are disclosed herein, and without intending to publicly dedicate any patentable subject matter.

The invention claimed is:

- 1. A method of operation of a maintenance decision support system, comprising:
 - providing an on-board computer in an operating maintenance vehicle with a treatment material application algorithm;
 - receiving, over a network and by the on-board computer, at least one real-time input;
 - collecting, by the on-board computer at least one sensor input, acquired from at least one sensor mounted on the maintenance vehicle and comprising data relating to the operation of the maintenance vehicle and at least one operator input, acquired from an operator of the maintenance vehicle and relating to the operation of the maintenance vehicle;
 - mapping, by the algorithm on the on-board computer, at least one of the real-time input, the sensor input and the operator input against a treatment material application 20 parameter to determine a set of recommended treatment material application instructions;
 - providing the set of recommended treatment material application instructions to the operator; and
 - providing a map with information about the operating 25 maintenance vehicle.
- 2. The method of claim 1, wherein the map shows maintenance vehicle locations, maintenance vehicle operations, and other information regarding the operation of the maintenance vehicle.
- 3. The method of claim 2, wherein the map depicts the location of each of a plurality of maintenance vehicles using icons to identify each of the plurality of maintenance vehicles.
- **4**. The method of claim **3**, wherein the icon's color 35 indicates differing operating characteristics of the maintenance vehicles.
- 5. The method of claim 3, wherein text information is depicted on the map adjacent to or associated with the icons.
- **6**. The method of claim **5**, wherein the text information 40 describes selected information associated with the maintenance vehicle, including a truck identifier, a direction of travel, a speed, a status of GPS signal, and a timestamp of last data update for the identified maintenance vehicle.
- 7. The method of claim 1, wherein the map depicts, for a 45 selected vehicle, a trace route over a selected period of time.
- **8**. The method of claim 3, wherein when a particular truck icon is selected, a user is able to view a live video feed of the roadway in the vicinity of the maintenance vehicle.
- 9. The method of claim 1, wherein the map includes one 50 or more sensor icons depicting a stationary meteorological sensor, payement sensor, roadway cam, and/or weather cam.
- 10. The method of claim 9, wherein selecting the sensor icon allows the user to view the associated media or multimedia information being collected by the selected sensor.

20

11. A maintenance decision support system, comprising: an on-board computer in an operating maintenance vehicle provided with a processor operable to process a treatment material application algorithm, wherein said on-board computer:

receives, over a network, at least one real-time input;

- collects, at least one sensor input, acquired from at least one sensor mounted on the maintenance vehicle and comprising data relating to the operation of the maintenance vehicle and at least one operator input, acquired from an operator of the maintenance vehicle and relating to the operation of the maintenance vehicle;
- maps, at least one of the real-time input, the sensor input and the operator input against a treatment material application parameter to determine a set of recommended treatment material application instructions;
- provides the set of recommended treatment material application instructions to the operator; and
- provides a map with information about the operating maintenance vehicle.
- 12. The system of claim 11, wherein the map shows maintenance vehicle locations, maintenance vehicle operations, and other information regarding the operation of the maintenance vehicle.
- 13. The system of claim 12, wherein the map depicts the location of each of a plurality of maintenance vehicles using icons to identify each of the plurality of maintenance vehicles.
- 14. The system of claim 13, wherein the icon's color indicates differing operating characteristics of the maintenance vehicles.
- 15. The system of claim 13, wherein text information is depicted on the map adjacent to or associated with the icons.
- 16. The system of claim 15, wherein the text information describes selected information associated with the maintenance vehicle, including a truck identifier, a direction of travel, a speed, a status of GPS signal, and a timestamp of last data update for the identified maintenance vehicle.
- 17. The system of claim 11, wherein the map depicts, for a selected vehicle, a trace route over a selected period of time.
- 18. The system of claim 13, wherein when a particular truck icon is selected, a user is able to view a live video feed of the roadway in the vicinity of the maintenance vehicle.
- 19. The system of claim 11, wherein the map includes one or more sensor icons depicting a stationary meteorological sensor, pavement sensor, roadway cam, and/or weather cam.
- 20. The system of claim 19, wherein selecting the sensor icon allows the user to view the associated media or multimedia information being collected by the selected sensor.
