

US008120473B2

(12) **United States Patent**
Rennie et al.

(10) **Patent No.:** **US 8,120,473 B2**
(45) **Date of Patent:** ***Feb. 21, 2012**

(54) **SMART MODEM DEVICE FOR VEHICULAR
AND ROADSIDE APPLICATIONS**

(75) Inventors: **Christopher J. Rennie**, Seattle, WA
(US); **Kevin K. Groeneweg**, Golden, CO
(US)

(73) Assignee: **Concaten, Inc.**, Golden, CO (US)

(*) Notice: Subject to any disclaimer, the term of this
patent is extended or adjusted under 35
U.S.C. 154(b) by 0 days.

This patent is subject to a terminal dis-
claimer.

(21) Appl. No.: **12/749,325**

(22) Filed: **Mar. 29, 2010**

(65) **Prior Publication Data**

US 2010/0182163 A1 Jul. 22, 2010

Related U.S. Application Data

(63) Continuation of application No. 12/046,121, filed on
Mar. 11, 2008, now Pat. No. 7,714,705, which is a
continuation of application No. 11/363,581, filed on
Feb. 27, 2006, now Pat. No. 7,355,509.

(60) Provisional application No. 60/656,650, filed on Feb.
25, 2005.

(51) **Int. Cl.**
B60R 25/10 (2006.01)

(57) **ABSTRACT**

A method and system are provided in which maintenance
vehicles collect information from sensors and operators, for-
ward the collected information to a server, and, in response,
receive maps and operator instructions.

SMART MODEM DEVICE FOR VEHICULAR AND ROADSIDE APPLICATIONS

CROSS REFERENCE TO RELATED APPLICATION

The present application is a continuation of U.S. application Ser. No. 12/046,121, filed on Mar. 11, 2008, which is a continuation of U.S. application Ser. No. 11/363,581, filed on Feb. 27, 2006 which claims the benefits of U.S. Provisional Application Ser. No. 60/656,650, filed Feb. 25, 2005, having the same title, all of which are incorporated herein by this reference.

FIELD OF THE INVENTION

The invention relates generally to modems used in stationary and mobile applications and particularly to intelligent modems for collecting selected vehicular information.

BACKGROUND OF THE INVENTION

Modems today have changed little in the last 25 years. Typical modems offer little if any processing power and can only be used with a given technology, network or connection. The processing power, if any, is typically limited and of little practical use in many applications today. Such modems do not support full operating systems, and offer the user limited, if any, programming flexibility. Changes as simple as network password changes have required the modems to be uninstalled and sent to the manufacture for reprovisioning. Such modems are not SOAP XML Web Services compatible and cannot take data from a given data source and convert and send it in the now common XML format. They also are not modular—if any given component fails, if there is a change in communications carriers, or if a given communication carrier phases out one technology and migrates to another (as with the migration by the former ATT Wireless from CDPD to GPRS), the modem typically has to be replaced—they are not modular in nature and given components cannot be easily and cheaply replaced. These limitations become especially acute and cost prohibitive in telemetric and other applications where the modem must operate without manual intervention and/or in series with other equipment which has no or limited processing power (i.e. other “dumb” devices). For whatever the reason, not the least of which is pricing pressures, much of the equipment used for example in industry, security, telemetric, and intelligent transportation systems, carry little onboard processing power and/or require a separate laptop or other computer to operate, download and/or forward the applicable information. The addition of such laptops and other external computers is generally either impractical (such as in unmanned and roadside applications) or cost prohibitive (generally doubling or more the cost of the modem itself). Furthermore, any given user may need connectivity for equipment located in different carrier service areas and/or with different types of connections (e.g. different wireless carriers, network connections, fiber connections, etc) and multiple types of data sources and inputs (multiple serial and USB inputs, as well as potentially video, sound, etc.). For national and international applications, and even applications on state-wide and local levels, flexibility in communication options and data collection options is important, as is the ability of the user to program the modem, add network security, store and forward data, and transfer the information in XML format via SOAP XML Web Services and/or such other format as their systems require. The ability to receive and process dynamic

instructions is also important but often missing or severely limited, and traditional modems do not enable the type of remote access and upgrades (complete operating systems and applications) that are necessary to collect data and/or communicate with disparate equipment in use today and newer equipment ever being developed and deployed.

Associated security measures further punctuate the need for greater flexibility and power in the modems. For example, dynamic IP addresses are being deployed in many contexts including by wireless commercial carriers in their 3G and beyond wireless data services. Dynamic IP's present a significant departure from the static IP's associated with historic polling practices and wireless CDPD functionality which had been the mainstay of wireless data collection prior to the advent of 3G functionality. Again, the ability to add intelligence to the modem, and to enable greater programming and application support becomes important to enable the otherwise “dumb” devices to return their new IP addresses and thus facilitate remote access and/or to transmit data and information back on an automated push (instead of pull) basis. Therefore, a need exists for a more powerful and flexible modem device that can be more easily programmed, that carries greater processing and storage capabilities, that can take various data feeds, that does not require a separate laptop or other computer to function, and that can readily and interchangeably work with a variety of communication connections and options. A tremendous need exists for a new modem device with sufficient flexibility and power to be used with relative ease in the various situations.

SUMMARY OF THE INVENTION

These and other needs are addressed by the various embodiments and configurations of the present invention. The present invention is directed generally to collecting selected types of information in vehicular and roadside applications and transmitting at least some of the collected information to a remote server.

In a first embodiment of the invention, a data collection and transmission method is provided that includes the steps:

- (a) a sensor and/or user interface collecting information regarding vehicle state and/or vehicle occupants;
- (b) a slot receiving a selected private or public network card (or a commercial carrier or otherwise), the slot being configured to receive cards for multiple networks;
- (c) determining a type (e.g., product identifier) and/or origin (e.g., vendor code) of the selected network card; and
- (d) selecting, for the selected network card and based on the determined type and/or origin, a set of a connection manager and a connection monitor from among a number of sets of connection managers and monitors corresponding to different types and/or origins of network cards. The connection manager interacts with the corresponding network card in establishing a connection with the corresponding wireless network, and the connection monitor monitors a state of the connection. The connection manager and/or monitor of a first set is different from a respective connection manager and/or monitor of a second set.

In another embodiment, a data collection and transmission method is provided that includes the steps:

- (a) collecting information regarding vehicle state and/or vehicle occupants;
- (b) establishing a first connection with a first network to transmit collected information to a remote server via that network;
- (c) thereafter determining a status and/or health of the first connection;

3

(d) when the first connection is down and/or unhealthy, requesting the removal of power to a selected wireless card positioned in a slot;

(e) when the request is denied, terminating execution of a communication initiation application; and

(f) after terminating execution of the communication initiation application, again requesting the removal of power to the selected wireless card.

The present invention can provide a number of advantages depending on the particular configuration. For example, the invention can provide a powerful and flexible, hardened modem that, among other things, utilizes advances from the programming and computing component industries to create a modular modem that users can much more easily program and integrate into their networks, and which can be used interchangeably in fixed and mobile applications with a variety of data and communication alternatives.

A number of developments enable the advance in modem functionality, flexibility, modularity and capabilities, including:

(1) better and cheaper components which can be borrowed from other the computing and other industries (e.g., cheaper, faster and more efficient processors and mainboards, and off the shelf items such as RAM, high capacity CF and/or HDD disks, wireless connection cards and other advances in communications equipment and functionality);

(2) a need for new, easier and more flexible programming, including support for full operating systems, applications and common languages; and

(3) a need for more connections and ports for much greater communication and data options and flexibility.

These and other advantages will be apparent from the disclosure of the invention(s) contained herein.

As used herein, "at least one", "one or more", and "and/or" are open-ended expressions that are both conjunctive and disjunctive in operation. For example, each of the expressions "at least one of A, B and C", "at least one of A, B, or C", "one or more of A, B, and C", "one or more of A, B, or C" and "A, B, and/or C" means A alone, B alone, C alone, A and B together, A and C together, B and C together, or A, B and C together.

The above-described embodiments and configurations are neither complete nor exhaustive. As will be appreciated, other embodiments of the invention are possible utilizing, alone or in combination, one or more of the features set forth above or described in detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention can be more readily understood in conjunction with the accompanying drawings, in which:

FIG. 1 is the exterior of the Smart Modem Device or SMD case showing the primary rear connection ports (in standard AC power connection) according to an embodiment of the present invention;

FIG. 2 is the exterior of the case of FIG. 1 showing the front face and additional ports there located;

FIG. 3 shows the interior of the SMD with the cover removed (including DC module with voltage regulator and sequencer for automotive applications) according to an embodiment of the present invention;

FIG. 4 shows the interior of the SMD with the cover and top plate removed (including DC module with voltage regulator and sequencer for automotive applications) according to an embodiment of the present invention;

4

FIG. 5 shows the interior of the SMD with the cover, top plate and mainboard removed (in standard AC power configuration as in FIG. 1 above) according to an embodiment of the present invention;

FIG. 6 shows SMD as used in roadside application (using AC power and PCMCIA connection card specially modified for an external antenna) according to an embodiment of the present invention;

FIG. 7 is a block diagram depicting a network architecture according to an embodiment of the present invention;

FIG. 8 is a block diagram depicting a network architecture according to an embodiment of the present invention;

FIG. 9 is a block diagram depicting a network architecture according to an embodiment of the present invention;

FIG. 10 is a block diagram of the components of a modem system according to an embodiment of the present invention;

FIG. 11 is a flowchart depicting an operational mode of the modem system according to an embodiment of the present invention;

FIG. 12 is a flowchart depicting an operational mode of the modem system according to an embodiment of the present invention;

FIG. 13 is a set of data structures according to an embodiment of the present invention;

FIG. 14 depicts a map according to an embodiment of the present invention;

FIG. 15 depicts a snowplow according to an embodiment of the present invention; and

FIG. 16 depicts a block diagram of the components of a data collection system according to an embodiment of the present invention.

DETAILED DESCRIPTION

System Overview

In one embodiment, the smart modem system collects and transmits selected output information regarding a vehicle state and/or its occupant(s) and/or receives selected input information for use by the vehicle and/or its operator. "Vehicle state" refers to a condition, function, location, or operation of a vehicle or a component or accessory thereof. As shown in FIG. 7, first, second, . . . nth smart modem systems **700a-n** are incorporated in a first, second, . . . nth vehicles **704a-n**. Each of the smart modem systems is in communication with a wireless public or private network **708**. The wireless network **708** is, in turn, in communication with an enterprise Local Area Network or LAN **710** that includes a firewall **712**, first, second, . . . mth servers **716a-m** and first, second, . . . mth databases **720a-m**. The modem systems collect selected types of information and continually or periodically forward the information, via the network **708**, to the enterprise network **710** for storage and processing. The stored and processed information can be accessed locally and directly by clients, such as PCs and laptops, internal to the enterprise network **710** or remotely by clients external to the enterprise network. The stored information is typically indexed by a unique SMD device name and corresponding vehicle name pairing. As will be appreciated, the multiple databases **720 a-m** need not have a one-to-one correspondence with the servers **716 a-m**, but may include more or fewer databases.

The vehicles can be motorized, such as commercial or private trucks and cars, or unmotorized, such as trailers (e.g., refrigerated trailers). Preferably, the vehicles have an on-board power source that is capable of powering the modem system and its peripheral devices, such as sensors. In one

5

configuration, the vehicles are snowplows operated by a governmental entity (such as a municipality, city, county or state), concrete mixers, concrete pumpers, refrigerated trailers, semi trucks, busses, dump trucks, garbage trucks, delivery vehicles, maintenance vehicles, emergency vehicles, and the like.

The wireless network **708** can be any type of wireless service and/or air interface, such as Advanced Mobile Telephone Service or AMPS, Digital Advanced Mobile Telephone Service or D-AMPS, Digital Communication Service or DCS1800, Global System for Mobile Communications/General Packet Radio Service or GSM/GPRS, North American Digital Cellular, Personal Communications Services, Personal Digital Cellular, Total Access Communication System, High Speed Downlink Packet Access or HSDPA, Enhanced Data GSM Environment or EDGE, 1xRTT CDMA, CDMA2000, Evolution Data Optimized or EVDO, Digital Enhanced Network or iDEN, Specialized Mobile Radio or SMR, 802.11x, WiMAX or 802.16, and other public and private networks, with Frequency Division Multiple Access or FDMA, Time Division Multiple Access or TDMA, Code Division Multiple Access or CDMA, Cellular Digital Packet Data or CDPD, Wideband CDMA or WCDMA/UMTS, or others. The public or private network **708** can be either landline or wireless. Wireless networks can be operated by one or more private or public networks, including carriers, such as Sprint™, Nextel™, Verizon™, Cingular™, Alltel™, Western Wireless™, AT&T Wireless™, Unicell™, Westlink™ and others, as well as affiliates thereof. Bandwidth and/or transmission speeds, and/or the frequency and method of data transmissions, may be intentionally limited (by setting appropriate modem parameters) to qualify for favorable telemetry rates.

The information collected **1612** (FIG. **16**) by the modem system **1600** (FIG. **16**) can vary depending on the application. The information **1612** can include vehicle speed, vehicle acceleration, engine revolutions-per-minute, engine temperature, engine oil pressure, fuel level, battery amperage, battery voltage, odometer setting, tire pressure, mileage per gallon, other onboard warning systems and sensors, weather conditions (such as temperature, humidity, wind speed and direction, wind chill, raining, snowing, blowing snow, foggy, clear, overcast, etc.), road conditions (e.g., icy, slushy, snow-packed, frosty, wet, dry, etc.), physical location **1620** (FIG. **16**) (e.g., Global Positioning System or GPS-based location), snow plow **1504** (FIG. **15**) setting (e.g., snowplow position and orientation such as plow **1504** up or down and angle relative to the truck longitudinal axis), mixture and amount of material being applied by spreader **1508** to a selected surface (e.g., salt level, sand level, magnesium sulfate level, other chemicals or materials, and combinations thereof), revolutions-per-minute of concrete mixing vessels, pumping pressure of concrete, video images of the vehicle's exterior environment or the vehicles' interior or exterior, audio of the vehicle's interior, airborne chemicals or particulates, radiation levels, friction measures, thermal and/or infrared imaging, credit card receipts, passes, driver identifications, bar codes, receipts, remote databases, instructions, job tickets, and directions and other information which can be displayed, sensed and/or input, manually or on an automated basis.

The information is typically converted into a selected form, packetized, and transmitted over the wireless network. The form of the information can be in accordance with any selected language, such as the eXtensible Markup Language or XML, the HyperText Markup Language or HTML, Remote Method Invocation or RMI, or Direct Socket Connections. The packets can be transported using any suitable

6

protocol, such as the Transport Control Protocol/Internet Protocol suite of protocols, Simple Object Access Protocol, or User Datagram Protocol.

The enterprise network **710** can perform a variety of data processing functions. The network **710**, for example, can compare information or a given sensed parameter to identify temporal trends or differences and, if necessary, generate appropriate alarms. The alarms can be logged internally and/or forwarded to the respective vehicle via the modem system. The vehicle operator and/or automated components thereof can then take appropriate remedial action to address the cause of the alarm. It can prepare selected reports on the information. It can log events. The enterprise network **710** can also provide communications to the modem system **1600**. The communications can, for example, provide instructions **1624** to the vehicle operator, such as vehicle and/or ancillary device operation and dispatch commands, and/or to automated components of the vehicle itself to remotely control selected vehicle operations.

In one configuration, the data processing can provide a spatial map **1400** (FIG. **14**) showing vehicle locations, vehicle operations, and other state information. For example and with reference to FIG. **14**, the map **1400** can depict the location of each of a number of snowplow trucks **1500** (FIG. **15**) using an icon **1404a-d** denoting each truck. The icon **1404** color can be varied to indicate differing vehicle states. For example, the color green indicates that the truck **1500** is active and working (e.g., blade down and/or spreading deicing materials), yellow that the truck **1500** is active but not working snow (e.g., not blading or spreading materials), red that the truck **1500** is stopped, and gray that the truck **1500** is off or out of range for at least a selected period of time. Text information **1408a-d** can be depicted on the map adjacent to or associated with each icon **1404**. The text information **1408** can describe selected state information associated with the truck **1500**, such as a truck identifier **1412**, direction of travel **1416**, speed **1420**, status of GPS signal **1424**, and timestamp **1428** of last data update for the identified truck. The map **1400** can also depict, for a selected vehicle, a trace route over a selected period of time. A trace route indicates the path of travel of the vehicle over the selected time period.

FIG. **8** depicts an architecture according to another embodiment of the present invention. The architecture includes a first vehicle **800a** including a first modem system **804a** in communication with a first wireless network **808a**, a second vehicle **800b** including a second modem system **804b** in communication with a second wireless network **808b**, . . . and an nth vehicle **800n** including an nth modem system **804n** in communication with an nth wireless network **808n**. Each network is typically operated separately by different entities or carriers. The vehicles are commonly operated by different business entities (e.g., are owned and operated by different companies). The first, second, . . . nth networks **808a-n** are in turn in communication with a third party enterprise network **812**, which provides contractual (fee-based) data storage and optionally processing services. The enterprise network **812** includes a LAN **816** interconnecting a firewall **820**, a server farm or cluster of first, second, . . . nth servers **824a-n** and one or a number of databases **828a-n**. Each of the databases **828a-n** is configured for a specific business entity operating one or more vehicles. In one configuration, the databases are replaced by a single database partitioned for each of the business entities. In any event, the information collected by the various modem systems is stored in the respective database or database partition. Data processing software customized for each entity can be resident in the enterprise network

812. Representatives of the independent entities can access, from a remote client, the data for which it has authorization, such as a PC or laptop.

In the above embodiments, the modem systems commonly include a smart modem device and peripherals thereof, such as a video monitor (e.g., a touchscreen), external GPS and connection antenna, and wired or wireless connections to internal vehicular components.

Smart Modem Device

In contrast to prior art in the field, the present invention can provide a powerful and flexible, hardened modem that, among other things, utilizes advances from the programming and computing component industries to create a modular modem that its users can much more easily program and integrate into new or existing networks, and which can be used interchangeably in fixed and mobile applications with a variety of data and communication alternatives.

This smart modem device (sometimes referred to “smart modem” or “smart device”—or “SMD” for short) can be built around ultra-compact and highly integrated mainboards and modern components originally developed in the computing, programming and other industries, including embedded high performance, low heat, ultra low power processors, replaceable RAM and Compact Flash (CF) memory, and various internal and external ports that can be used for communications and the transmission and/or receipt of information. Various modular options can also be added and incorporated at manufacture or in aftermarket, including additional memory, enhanced video cards, additional connections and inputs, additional memory, etc.

The SMD can incorporate full programming language support and be fully user programmable in various common languages such as Perl, Java, C variants, .NET and others. This programming flexibility can be used both for purposes of setting up and directing the transfer or receipt of data and information, as well as for the processing thereof, if and to the extent such field processing and/or translations are required in the field. In addition to interfacing in traditional standards such as ASCII, HEX and other formats, the SMD is fully SOAP XML Web Services compatible. In addition to the communications elements of the modem, users can run Linux, Microsoft and other programs to provide additional desired utility and functionality, such as for taking MPEG 4 or other video from the field, running applications and peripheral services in the mobile or field environment, without the need for separate equipment such as laptops, computers or processors. The SMD can provide flexible modem functionality on a stand-alone basis. The SMD can be remotely access, upgraded and/or reconfigured if and as so necessary.

The SMD can anticipate and provide for interchangeable and upgradeable communications and data options through PCMCIA, CF, RJ-45, RS-232, USB and other connections. Wireless services, for example, can be used on one network in one part of a state, and on another network in another part of the state, with the simple interchange of a connection card in the PCMCIA (cardbus) in the back of the device, and a corresponding change in drivers for the new network and card. Other devices can be as easily changed to operate on network connections, fiber connections, wireless Ethernet connections and other alternatives. Such conversions, as well as simply the replacement of a damaged card or component, can be done at the nominal cost of that given card or component, rather than the replacement of the entire device.

The SMD can provide a powerful and flexible, hardened modem that, among other things, utilizes advances from the

programming and computing component industries to create a modular modem that users can much more easily program and integrate into new networks, and which can be used interchangeably in fixed and mobile applications with a variety of data and communication alternatives. The flexibility, power and integrated modularity marry hardware and programming to provide a truly synergistic advance in the state of the art in modem technology, and associated applications of telemetry, data collection and communications. Without repeating what has already been said above (and incorporated herein), the device is below presented in its various component pieces. The modem preferably has a modular design, including both the hardware and software, as well as the interchangeable external components, including without limitation the various COM and data options with which it works (e.g., connection cards, land lines, GPS units, cameras and the various vehicles and field devices to which it is attached). Significantly, if any given component is damaged or destroyed, or otherwise made obsolete by advances in science and technology, such components can generally be replaced and upgraded for nominal cost and the device redeployed. The entire unit does not have to be replaced, and maintenance and repairs for individual units (or planned groups of units) replace broad and expensive capital replacement programs as communication carriers migrate to ever new and improved communications options and services, or clients migrate to private or other public networks. Commercial connection cards for example can be swapped out, one for another, and often at no net upfront cost (after activation credit), by simply popping out the old PCMCIA card and popping in the new with the new connection driver. Mainboards can be replaced in nominal time and at low cost. Memory can be expanded for many GBs of additional storage at low cost. The device can be completely reprovisioned for use with new cameras or other equipment by simply downloading new files (remotely or on-site) or swapping out the internal CF for a new disk. Historic problems of replacing entire devices and incurring thousands (sometimes millions) of dollars of capital upgrade costs has been broken down and replaced with a more practical use and marriage of more sophisticated and flexible components from the fields of hardware, software and general design.

The following provides a more detailed discussion of the various components advantages, features and objects of the SMD.

Case size is currently primarily a size of the existing components and a trade-off in costs. Bigger becomes impractical. Smaller currently gets disproportionately expensive. With current component sizes and price points, we typically use cases such as the 2.5"×8"×10" Morex #3688 steel case 1 featured in the accompanying photos. It is anticipated that smaller cases will be usable as ever smaller components become more price competitive. While smaller cases can be used, a larger case can provide a bit extra room to work with, dissipate heat, add additional internal components when and as desired (e.g. additional internal memory **25 & 29**), and yet is small enough to be collocated with other equipment in even larger or more protective cases such as NEMA 4 and other environmentally protective cases such as the roadside box shown in FIG. 6. Internally, the tray is modified to mount the internal CF **27a**, **27b** and **27c**, the DC voltage regulator and sequencer for automotive applications **25** (if not otherwise incorporated directly into the power supply **42**), and other items.

All Figures show the 2.5"×8"×10" Morex case configuration, though other cases can also be used. Any suitable case that can accommodate the following components can be used.

FIGS. 3 and 4 show the embedded system in the case with integrated VIA mainboard and 1 GHz processor, 2 GB compact flash for programming and data storage, 256 MB of heat shielded RAM, and an ITPS DC module with voltage regulator and sequencer as used for automotive applications. Other mainboards and components could be substituted.

The SMD is designed for both fixed and mobile applications. AC/DC power is typically incorporated. Such power supplies are generally sourced from the applicable case manufacturer, as the Morex Procase power board shown in the accompanying photos 42, but any reliable power supply will do. A voltage regulator should be used with the power board for mobile applications. A combination regulator and sequencer is either incorporated into the power board 42 or separately collocated such as the ITSP regulator and sequencer from Mini-Box 25 is typically incorporated to provide key on/off functionality with delayed power-off for an orderly initiation of the shut-down of the device and whatever functionality is then active.

Any small form factor mainboard with appropriate connections can be used, such as the VIA MII mainboard shown in the accompanying FIGS. 1, 3 and 4, and items 2-10, 30, 35, and 38-39. For data, video and other inputs, connections should be provided for major connection types intended to be used, including currently and without limitation, multiple USB, 1394, RCA and Serial connection options 6, 10, 11, 13 and 39. For communications, connections or slots should be available for, among other things Ethernet, PCMCIA (cardbus) & CF 7, 8, 9 and 39. Multiple IDE slots 35a and 35b, at least one PCI slot 38, and at least one DIMM slot for standard RAM 36 should be included. Typically the mainboards would carry an embedded ultra low power, ultra low heat processor such as a 600 MHz or the 1 GHz VIA C3 37 and support standard RAM 36 of typically 256 MB or more (the VIA mainboard 30 supports up to 1 GB of RAM). It is important that the embedded system use a processor that is low power low heat, or heat buildup can become an issue in the tight enclosures involved in various applications such as shown in FIG. 6. Advance in the computer component industry in these regards, and processors in particular (with significant advances in processing speeds with such ultra low power, ultra low heat processors as the C3 37) have made this advance in modem technology possible. Future mainboards can be even smaller, carry more or different ports and connections and even faster more efficient processing capabilities. In any event, the mainboard and associated faceplate (2 and 30) are inserted in and affixed to the applicable case. These "new" mainboards are substantially faster, and more modular and flexible, than mainboards found in traditional modems.

Any standard RAM 36 can be used. Typically, 256 MB or more of RAM is incorporated. In the accompanying FIG. 4, we are shown using 256 MB of heat shielded RAM from SuperTalent. The VIA mainboard 30, shown in the examples can support up to 1 GB of RAM. Additional RAM may be supported and used in the future. Such RAM can be used in either typical fashion (as most users use their PC—e.g. where operating files are primarily carried on separate memory such as an HDD drive or in this case CF 27c, and there is an ongoing interaction between the two) or in more specialized ways such as with special optical files or read only memory (ROM) where all operation code (operating files as well as application) are loaded into RAM on boot from the separate storage. In the later case for example, all operable code is bundled into one optical file or ROM, either of which can be loaded into and run from RAM once the device is powered up. Any malicious or accidental attempts to change or damage the

operating code have but a temporary impact as the optical file will again and automatically reloaded in original form when the RAM next reads the file, such as on reboot or restart. In such cases, the RAM has to be larger than the combined files (ie. all programming and operating files). A fairly sophisticated application can run in this manner on less than 1 GB of RAM.

CF memory is typically used to get away from moving parts such as in HDD drives, and to provide a more hardened unit. Any CF can be used—the enclosed pictures show a 2 Gb CF card by SanDisk. While avoiding the moving parts of an HDD, the CF provides many of the benefit of solid state circuitry but with substantially more flexibility in terms of programmability and ease of use. An IDE to CF adaptor board 27b and shortened IDE cable 34 is used to integrate the CF memory with the mainboard 30 and associated functionality. Where, as with the VIA mainboard 30, an additional IDE slot is available, additional internal CF or HDD storage capacity can be added. Removable external CF memory can also be used in the CF slot provided and accessible from the faceplate 9. If the user prefers, an HDD (typically 20 GB or higher) can be used in lieu of or addition to the internal CF. The SMD can also boot from other memory, including USB sticks, if desired or needed.

The importance of having various COM and data options cannot be overstated, and the SMD specifically provides as much flexibility as technology and available components allow in this regard. The SMD anticipates and provides for interchangeable and upgradeable communications and data options through PCMCIA, CF, RJ-45, RS-232, USB and other connections, e.g 6, 7, 8, 9, 10 and 11. Wireless services, for example, can be used on one network in one part of a state, and on another network in another part of the state, with the simple interchange of a connection card in the PCMCIA (cardbus) 8 in the back of the device, and a corresponding change in drivers for the new network and card. Other SMD's can be as easily changed to operate on network connections, fiber connections, wireless Ethernet connections 7 and other alternatives including dial-up land lines via a PCMCIA card 8. Such conversions, as well as simply the replacement of a damaged card or component, can be done at the nominal cost of that given card or component, rather than the replacement of an entire device, as has been necessary with traditional external modems which operate on only one network and incorporate limited if any processing capabilities.

In the context of PCMCIA and CF connection cards 8 (which themselves are sometimes referred to as NIC cards, modems or aircards), the SMD provides a host environment much like, but much more flexible and powerful than, the external modems which themselves incorporate modules comparable to that in the PCMCIA or CF connection cards but which have but limited processing power and are far less flexible in terms of overall programming, processing or network changes. Such external modems, once so manufactured, are typically only usable on the network for which they were designed. If for example, a user changes carriers, the external modem is of no use or value. If the carrier changes technology (such as CDPD to GPRS), the external modem is of no use or value. Conversely, the SMD allows for the easy and quick upgrade of technology by the change of the PCMCIA card, and/or the quick change to an entirely different network or even to a fixed connection such as fiber, network, or wireless Ethernet where practical and available.

Programmability provides a new, significantly higher level of modem flexibility and performance. Typical modems offer little if any processing power and can only be used with a given technology, network or connection. The processing

11

power, if any, is typically limited and of little practical use in many applications today. Such modems do not support full operating systems, and offer the user limited if any programming flexibility. Changes as simple as network password changes have required the modems to be uninstalled and sent to the manufacture for reprovisioning. Limitations with existing systems become especially acute and cost prohibitive in telemetric and other applications where the modem must operate without manual intervention and/or in series with other equipment which has no or limited processing power (i.e. other "dumb" devices). For whatever the reason, not the least of which is pricing pressures, much of the equipment used for example in industry, security, telemetric, and intelligent transportation systems, carry little onboard processing power and/or require a separate laptop or other computer to operate, download and/or forward the applicable information. The addition of such laptops and other external computers is generally either impractical (such as in unmanned and roadside applications) or cost prohibitive (generally doubling or more the cost of the modem itself). Furthermore, any given user may need connectivity for equipment located in different network service areas and/or with different types of connections (e.g. different wireless carriers, network connections, fiber connections, etc) and multiple types of data sources and inputs (multiple serial and USB inputs, as well as potentially video, sound, etc.). For national and international applications, and even applications on statewide and local levels, flexibility in communication and data collection options is important, as is the ability the user to program the modem, add network security, store and forward data, and to transfer the information in XML format via SOAP XML Web Services and/or such other format as their systems require.

The SMD incorporates full operating system and programming language support, by virtue of and with appropriate utilization of the above components. The SMD is fully user programmable in various common languages such as Perl, Java, C variants, .NET and others. This programming flexibility can be used both for purposes of setting up and directing the transfer or receipt of data and information, as well as for the processing thereof, remote access to download or upgrade programming or reach remote sites and equipment, receive and post messages to remote users, enable remote users to interface with the office, the internet or other systems.

The ability of the SMD to receive and process dynamic instructions is beneficial but often missing or severely limited in traditional modems which enable this type of remote access, and cannot even carry full operating systems or common modern applications, let alone take, for example, a remote upgrade of touch screen menus used to collect mobile information or to communicate with a lot of the disparate equipment in use today and newer equipment ever being developed.

The SMD's expanded programmability and more powerful mainboard and components enable the modem to take, process, store and/or forward information as not otherwise possible. Traditional modems typically have been set up to simply establish a connection to forward or allow the polling of given data. Traditional modems were not designed to run today's operating systems or applications, or to really do more than rudimentary tasks. The traditional modem cannot provide the host environment necessary to support the varied drivers and software necessary to support for example the many peripheral devices being integrated today, including without limitation USB cameras, touch screen monitors, weather station components, travel time sensors, mobile sensors and data feeds, etc.

12

With the SMD, this is possible and more. Operating systems, applications, special or new drivers, etc. all can be loaded, programmed and reprogrammed, and even be remotely accessed and changed if necessary. Peripherals can be added which require associated software to run and operate—software that could not otherwise be loaded on traditional modems by the end user, if at all. Off-the-shelf software, custom applications, legacy interfaces, new interfaces, special security overlays, etc. could not be readily loaded on traditional modems by the end user, if at all. With SMD's, users can load Linux, Microsoft and other systems, programs, drivers, etc. . . . to provide additional desired utility and functionality, or to support the peripheral equipment to which the smart modem device is attached. Applications requiring field processing, special drivers and/or software, such as for MPEG 4 video, barcode scanners, RFID sensors, work order forms, ERP systems, etc., can be integrated with the smart modem device without the need for separate laptops, computers or processors.

The programmability of the SMD contributes to the flexibility and modularity of the device, and in extending those benefits to the peripheral equipment with which the SMD is connected (eg. camera, gps, weather equipment, monitors, etc. . . . even the communication card or carrier itself). When a given component or peripheral fails or is otherwise replaced, a new component or peripheral (even an entirely different peripheral) can be attached and new drivers and associated software can be easily loaded. If there is a change in communications carriers, or if a given communication carrier phases out one technology and migrates to another (as with the migration by the former ATT Wireless from CDPD to GPRS), only the connection card and drivers need be replaced, not the entire smart modem device.

The above also enables the SMD to be fully SOAP XML Web Services compatible, unlike traditional modems. XML interfaces are becoming increasingly important in networking disparate equipment and systems, reducing network overhead, etc. In addition to interfacing with traditional formats such as ASCII, HEX and others, the SMD can provide full XML interfaces. The SMD, for example, can be easily loaded with JAVA and an associated application to receive data and forward it in XML in a SOAP XML Web Services compatible format. This capability and the ability to adapt and integrate with other and new services and formats will become especially important for deployments over time.

New and ever changing security requirements, changes in network connections and systems, authentication schemes (internal and carrier related), further punctuate the need for the enhanced programmability and capabilities of the SMD. As they evolve, such changes and overlays can be integrated and loaded, and later changed and updated as necessary, with relative ease. The SMD is programmable and reprogrammable. CF cards can be changed in the field to completely reprogram the device. Other security changes can be made by USB stick or remote access. In short, the SMD provides flexibility to grow and adjust with future needs and developments.

FIG. 9 depicts a signal flow diagram, FIG. 15 a snowplow, and FIG. 16 a modem-based system according to an embodiment of the present invention. The modem-based system 1600 comprises one or more network cards 904a-p, each plugged into a corresponding slot (not shown) of the modem or SMD 900, an antenna 906 for duplexed communications with a network, a GPS module 908 and corresponding antenna 912, a plurality of sensors 916a-q, a user interface 920, and the SMD 900.

13

The network cards **904a-p** are provided by a wireless carrier or network administrator, and contain the logic and related parameters required for access to the corresponding network. Although multiple network cards are depicted, it is to be understood that the present invention includes an SMD configuration having only one slot, as shown in the SMD configuration discussed above. Each of the network cards is interchangeably received in each slot. Thus, cards from different networks or different types of cards from the same network can be placed in any of the slots. As will be appreciated, each card normally has an associated unique identifier (for example a ten digit number assigned to the card by the carrier). The card is typically activated by contacting the service provider or network administrator, or by doing an automated activation via an applicable web page.

The GPS module **908** can be any suitable GPS module, including the GPS module discussed previously. Typically, the GPS module forwards digital location signals (e.g., GPRMC NMEA sentences) to the SMD **900**. The timing of the signals is typically controlled by the GPS module. A preferred GPS module **908** integrates the antenna **906** and GPS module **908** into a GPS puck positioned on the exterior of the vehicle. The GPS module can be plugged into various available ports on the SMD, including specially created ports such as a special five-pin DIN connection. The GPS module can also be separated from the antenna and collocated inside of the SMD.

The sensors **916** can be of a variety of types and monitor different parameters. The sensors, for example, can include temperature sensors (e.g., for ambient and engine temperatures), pressure gauges (e.g., for oil, fuel pressure, and/or cement pumping pressure), sensors for measuring the revolutions per minute of a motor, engine, or rotating member, speedometers, odometers, compass, and various other wired or wireless sensors and inputs from equipment on or near the vehicle. In one configuration, the sensors include a still and/or motion video imaging device **1608** to provide still or full motion images to the remote server. In one configuration, the sensors **916** include a microphone to provide audio to the remote server. Analog-to-digital conversion is employed, as needed, to convert analog signals from sensors **916** to digital format.

The user interface **920** can include a variety of devices, such as a keyboard and/or monitor. The monitor is preferably a touchscreen. The monitor can provide the operator with various options to control operations of the vehicle (e.g., pumping speed, plow blade, bucket, or truck bed, mixture of materials to be applied to a surface, rpms of concrete mixer, and the like), provide data input regarding the vehicle state (e.g., snowplow is raised or lowered) or environmental conditions, transmit text messages to the remote server, receive text messages from the remote server, and views of the data transmitted and/or received.

The SMD **900** includes a number of internal logic modules for performing various operations. The connection managers **924a-x** configure the SMD **900** as required by the particular network card **904** in the slot or otherwise selected by the user and interacts with the card to establish a communication session with the remote server. The connection monitors **928a-x** monitor the health and/or state of the connection and, if the health is unacceptable (e.g., the connection has too much interference or the Quality of Service is unacceptable) or the link used by the connection is down, reestablishes the communication session by setting up another connection. Typically, a set formed by one connection manager and monitor corresponds to each type and/or origin of network card **904** used interchangeably in the slot(s). The system clock **936**

14

is synchronized to a universal time clock and provides internal timing information to control SMD operations and timestamp collected data. The memory **940** is used during normal processing operations and as a buffer for data **1612** collected when the connection with the network is either unhealthy or down. Finally, the system manager **932** oversees operations of the SMD, identifies the types of digital incoming signals (e.g., by sensor **916** type) and, based on the type of incoming signal, translates the digital signals received from the sensors **916** to a selected language or format, packetizes the collected data **1612** with a data-type identifier included in the payload, and applies headers to the packets for uploading onto the network, handles mail and messaging functions, includes drivers and programming for the user interface, performs remote system maintenance and troubleshooting functions, and other functions.

In one configuration, the manager **932** process multimedia information. For example, the manager **932** uses the following parameters to process video information: the URI address of the remote server, the imaging device name, time interval between snapshots, Boolean value for whether images should have a current date/time stamp, Boolean value for whether attachments should be sent as DIME or MIME attachments, temporary file storage location, and the name **1616** of the SMD **900** sending the video information. The name **1616** of the SMD **900** is used by the remote data processing network **710** to associate the received information with the corresponding vehicle; thus, the sending device name **1616** is selected to identify uniquely the SMD.

Operation of the Connection Manager and Monitor

The operation of the connection manager and monitor will now be described with reference to FIGS. **10-12**.

FIG. **10** depicts the process used to establish a link or connection with a network using a selected network card **904**. The process starts in step **1000** when the user inserts a network card into a slot.

In step **1004**, the manager **932** identifies the card vendor code and product identifier. This is obtained by querying the card and/or by manual input such as via the touchscreen monitor.

In step **1008**, the manager **932** selects the corresponding connection manager **924a-x** and monitor **928a-x** for the particular card type and vendor. This can be done by dynamically writing the appropriate connection manager **924a-x** and monitor **928a-x**, or by commenting out the unselected sets of connection manager **924a-x** and monitor **928a-x**, or by placing a character or symbol indicating nonexecutable comment text in front of the code associated with the unselected connection managers **924a-x** and monitors **928a-x**. The selected set of connection manager **924a-x** and monitor **928a-x** is not commented out.

In one configuration using a Linux operation system in the SMD, the connection manager **924a-x** and connection monitor **928a-x** are, collectively, formed by a number of daisy-chained files. In this configuration, the connection monitor **928a-x** refers to the initialization file while the connection manager **924a-x** refers to the chat script file, peers file, pap-secrets file, and ip-up.local file.

The initial file in the chain is the connection monitor **924a-x** and is a file containing initialization information and script to perform various operations, including the next file in the file sequence. The file, for example, contains the logic of FIG. **11**.

The next file in the chain is the peers file, which controls and configures (e.g., provides setup parameters for) a com-

15

munications initiation application (not shown) of the operating system. The communication initiation application is preferably a part of the connection manager. The communications initiation application effects, after the link with the network is established, communication with other nodes via the network. As will be appreciated, in the Linux operating system the communications initiation application is known as the Point-to-Point Protocol Daemon or PPPD. PPP is the protocol used for establishing internet links over dial-up modems, DSL connections, and many other types of point-to-point links. The PPPD daemon works together with the kernel PPP driver to establish and maintain a PPP link with another system (called the peer) and to negotiate Internet Protocol (IP) addresses for each end of the link. PPPD can also authenticate the peer and/or supply authentication information to the peer. As will be appreciated, PPP can be used with other network protocols besides IP.

The communications initiation application controls the card and, inter alia, provides address information to the card. The peers file includes connection information to be used for the connection, such as the identity of the port (e.g., serial port name), the size of the window for used for input/output (e.g., desired baud rate for the serial device), whether the connection is to be persistent, the connect script used to connect the card, disconnect script used to disconnect the card, and other options such as default rate, speed, ttyname, crtscts, lock, mru, mtu, and passive.

The next file in the chain is the chat file, which contains the command set required, for the particular card vendor and type, to establish the connection. The command set typically is an ordered series of queries to the card and response definitions provided by the card in response to the queries.

The final file in the chain sequence is the pap-secrets file, which contains a username and password. Another file in the sequence is the ip-up.local file, which, after the link is established with the network, is used by the modem to select a Domain Name Service or DNS server and, inter alia, starts a time synchronization sequence with a universal time server to maintain synchronization between the system clock 936 and universal time.

In step 1012, the manager 932 invokes the connection monitor, which in turn invokes the connection manager 924 to establish the connection with the network.

In step 1016, the card sets up the connection. Generally, the card receives an identifier or address (e.g., telephone number, ESN or other) from the communication initiation application. The identifier or address is associated with the card and informs the network that the card is associated with an authorized wireless device. In the configuration, the network sets up a serial connection with the SMD followed by a handshake and authentication procedure between the card and network. Other links are also possible. After the link is up, the network assigns an IP address to the SMD. As will be appreciated, certain networks, such as Sprint and Verizon, automatically assign and provide a link with a DNS server address while others, such as Cingular, fail to provide a link with a DNS server address. For the latter networks, the DNS server address is included in the connection manager files. Regarding authentication, some network services, such as Cingular, use the same username and password for a number of network cards of the same type. Others, such as Sprint, include the post-card-activation authentication information in the card itself, so non pap-secrets file is needed in the connection manager.

FIGS. 11 and 12 depict the operation of the connection monitor 928a-x after a link has been established.

16

The process starts with the establishment of a link in step 1100.

In decision diamond 1104, the connection monitor 928a-x determines whether or not the link is up. The performance of this step depends on the air interface used by the network. With most air interfaces such as the current CDMA services, the monitor 928a-x checks locally to determine if the monitor is up. If communication is lost with the network, the link is not up. In that event, the card automatically informs the manager 932 that the link is down. The system manager 932, in response, removes the file for the link. In the Linux operation system, the manager 932 removes a point-to-point protocol (ppp) link from the route file when it is informed that a link is disconnected. If there is a ppp entry in the route file, the link is still up. If there is no ppp entry in the route file, the link is down. The monitor 928 can thus determine readily whether or not the link is up.

With certain connection cards on the GPRS air interfaces, the card does not inform the manager that the link has been disconnected, and the ppp entry remains in the route file even when the link is down (the "ppp Exception"). In this case, the monitor functions differently and forwards a query (e.g., DNS lookup request) to the DNS server. If a response is received, the monitor knows that the link is still up. If no response is received from the DNS server, the monitor knows that the link is down.

If the link is up, the monitor proceeds to decision diamond 1116 and repeats the foregoing operation after a predetermined time interval.

If the link is down, the monitor proceeds to step 1108. In step 1108, the monitor determines if the connection manager (i.e., the communications initiation application [e.g., PPPD]) is running. Stated another way, the monitor determines whether the communications initiation application is configured for a persistent connection. When so configured, the communications initiation application will retry automatically to reestablish the connection with the network. Accordingly, when the communications initiation application is configured for a persistent connection the monitor proceeds to decision diamond 1116 as there is no need for it to effect reestablishment of the connection. When the communications initiation application is not configured for a persistent connection, the monitor proceeds to step 1120 in which it resets the card and effects reestablishment of the connection. In one configuration, the monitor simulates user removal and reinsertion of the card into the slot.

FIG. 12 depicts, in more detail, the process of step 1120 in the case of the "ppp Exception" noted above, that is used to reset the card in the event of a lost link.

In step 1200, the monitor 928a-x performs a soft reset of the card. The soft reset is performed by the manager 932, which removes power to the slot and then reapplies it. Some cards, however, do not permit the manager to remove power from the slot.

In decision diamond 1204, the monitor 928a-x determines whether the manager 932 was successful in removing and reappling power to the slot. When the soft reset has not been successful, the monitor 928a-x, in step 1208 shuts down the communications initiation application 930. Because the application is shut down during operation or "hard killed", the manager 932 removes remnants from the application's operation to ensure that the remnants do not interfere with the ensuing steps of the process.

After removal of the remnants, the monitor 928a-x, in step 1212, repeats the soft reset of the card.

When the soft reset is successful in decision diamond 1204 or after the soft reset of step 1212, the monitor 928a-x, in step

17

1216, provides the card attributes to the manager 932. Primarily, the attributes pertain to how the SMD 900 is to recognize the card, e.g., as a serial or Universal Serial Bus or USB device as the manager 932 will need to set up a serial or USB connection, as appropriate. The communications initiation application is configured for serial connections. When the card is a USB device, the manager 932 will recognize automatically the card as a USB device, and, when the card is a serial device, the manager 932 will recognize automatically the card as a serial device. So that the card will interface with the communications initiation application, the monitor 928a-x instructs the manager 932 to set the card attributes for a serial device. When the card is natively a serial device, the monitor 928a-x provides the manager 932 with a baud rate for the serial connection. There is no need to provide a baud rate when the card is natively a USB device as the baud rate for the connection with the USB card will be set automatically by the manager 932 at a sufficiently high rate.

The connection may be terminated voluntarily by the SMD 900 in response to a set of predetermined trigger events. One trigger event is a command by the user. Another trigger is when the received signal strength from the network falls below a selected threshold. Signal strength may be measured using the mechanisms currently used by cell phones to measure and report the signal strength to the user, even though the user has not yet placed a call. Yet another trigger is one or more selected quality of service (QoS) parameters falling below a corresponding predetermined threshold. Exemplary QoS parameters include packet loss, jitter, latency, etc. To prevent automatic reestablishment of the connection, the manager 932 can prevent the monitor 928 and communications initiation application from running. Alternatively, the manager 932 can permit the monitor 928 and communications initiation application to run in an attempt to reestablish the connection. Alternatively, the manager 932 can permit the monitor 928 and communications initiation application to run but select a different one of the cards (and a different network) for the connection attempt. In this alternative, the SMD 900 will move from network to network in response to variations in the health of the established link.

Data collection by the SMD 900 may be periodic or continuous. Periodic data collection may be based on one or more trigger events, such as the passage of a selected time interval, passage of a given number of data entries (either in total or sorted by parameter), detection of a change in one or more selected state parameters or variables, or receipt of a data transmission command by a user. When data collection is to be transmitted and the connection is either down or up but unhealthy, the SMD buffers the data in the memory 940 while the monitor 928 attempts to reestablish the connection with the same or a different network. When the connection is reestablished, the data is transmitted via the network to the remote server.

To conserve bandwidth, the manager may filter by a filter 1628 (FIG. 16) the collected data that is transmitted to the remote server. The data may be filtered on a number of criteria, such as duplication or type. Regarding duplication when the data has not changed since a prior transmission, the data would not have to be resent. Only data that has changed since the prior transmission could be resent. Regarding data type, certain types of data may be sent automatically to the remote server while other types of data may only be sent in response to a trigger event, such as a change in the data or detection of an alarm condition of a vehicular state parameter, or a manual trigger via a touchscreen input.

18

A number of variations and modifications of the invention can be used. It would be possible to provide for some features of the invention without providing others.

For example in one alternative embodiment, the SMD 900 is configured for remote software upgrades, particularly for firmware. The software is not only that resident in the SMD 900 but also for an ancillary component, such as the sensors 916. The upgrade is normally started by the operator of the vehicle commanding the SMD 900, via the user interface 920, to initiate a software upgrade. The manager 932 contacts the remote server and checks for an appropriate upgrade. As part of the interaction, the manager 932 may need to provide authentication information, such as the name 1616 of the SMD 900, a username and a password, or an authentication code. If an upgrade is located, the SMD 900 pulls the upgrade from the server 824 via the selected network. The manager 932 then proceeds to install the upgrade on the respective SMD 900 or ancillary component.

In another alternative embodiment, the SMD 900 is configured to detect automatically a network card 904 based on vendor and type and select automatically the corresponding set of connection manager 924a-x and monitor 928a-x. When a card is inserted or otherwise selected by a user, the manager 932 accesses the vendor code and product identifier resident on the card and retrieves a lookup table, such as that depicted in FIG. 13, from memory 940. The manager 932 maps the vendor code and product identifier set received from the card to receive an identifier for the corresponding set of connection manager 924a-x and monitor 928a-x. In one configuration, the identifier is a memory address or pointer to one or more selected files in the corresponding set. Because in one configuration the connection manager 924a-x files are daisy-chained to the connection monitor 928a-x, the identifier can be a pointer or memory address of the connection monitor 928a-x only.

In another alternative embodiment, the SMD is used in stationary roadside applications to collect various types of information. For example, in one configuration, the data collected can be the speed, volume and/or occupancy of passing vehicles. In another configuration, vehicle identification information, such as a license plate number or license plate image, can also be sent with the speed of the identified vehicle. In another embodiment, photos of mountain passes, intersections, or other locations can be periodically sent back to the server. The collected data is transmitted to a server of a central data processing facility. In this configuration, the SMD can be either connected to power or be collocated with an on board power source, which could be a generator or a solar powering array. The data may be transmitted wirelessly or over a fiber network to the central data processing facility.

In yet another alternative embodiment, the SMD uses operating systems other than Linux, such as a Microsoft™ operating system.

In yet another embodiment, dedicated hardware implementations including, but not limited to, Application Specific Integrated Circuits or ASICs, programmable logic arrays, and other hardware devices can likewise be constructed to implement the methods described herein. Furthermore, alternative software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the methods described herein.

The present invention, in various embodiments, includes components, methods, processes, systems and/or apparatus substantially as depicted and described herein, including various embodiments, subcombinations, and subsets thereof.

Those of skill in the art will understand how to make and use the present invention after understanding the present disclosure. The present invention, in various embodiments, includes providing devices and processes in the absence of items not depicted and/or described herein or in various embodiments hereof, including in the absence of such items as may have been used in previous devices or processes, e.g., for improving performance, achieving ease and/or reducing cost of implementation.

The foregoing discussion of the invention has been presented for purposes of illustration and description. The foregoing is not intended to limit the invention to the form or forms disclosed herein. In the foregoing Detailed Description for example, various features of the invention are grouped together in one or more embodiments for the purpose of streamlining the disclosure. This method of disclosure is not to be interpreted as reflecting an intention that the claimed invention requires more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive aspects lie in less than all features of a single foregoing disclosed embodiment. Thus, the following claims are hereby incorporated into this Detailed Description, with each claim standing on its own as a separate preferred embodiment of the invention.

Moreover, though the description of the invention has included description of one or more embodiments and certain variations and modifications, other variations and modifications are within the scope of the invention, e.g., as may be within the skill and knowledge of those in the art, after understanding the present disclosure. It is intended to obtain rights which include alternative embodiments to the extent permitted, including alternate, interchangeable and/or equivalent structures, functions, ranges or steps to those claimed, whether or not such alternate, interchangeable and/or equivalent structures, functions, ranges or steps are disclosed herein, and without intending to publicly dedicate any patentable subject matter.

What is claimed is:

1. A method, comprising:

- (a) receiving over a wireless network, from a plurality of snow maintenance vehicles and by a server, a plurality of sets of collected information, each of the collected sets of information comprising a respective snow maintenance vehicle physical location and at least one of weather and road conditions in an area of the respective snow maintenance vehicle;
- (b) processing, by the server, the received collected information to (i) provide a map associated with a physical location of a selected snow maintenance vehicle and (ii) determine an instruction for the selected snow maintenance vehicle and/or route; and
- (c) providing, over the wireless network the map and an instruction to a user in the selected snow maintenance vehicle, wherein the map is visually displayed to the user and wherein the instruction comprises one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

2. The method of claim 1, wherein the user is at least one of an operator of the snow maintenance vehicle, a dispatcher, or a representative of a governmental entity, business entity, or independent entity, and wherein the instruction comprises one or more of an alarm based on a temporal trend in weather

conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a Global Positioning System ("GPS")-based location of the selected snow maintenance vehicle, wherein the GPS-based location is received by a processor from a GPS module, wherein the GPS-based location is a current and/or recorded snow maintenance vehicle physical location, and wherein each of the sets of collected information includes a unique identifier associated with the respective processor, the unique identifier being different from the processor's IP address.

3. The method of claim 1, wherein the map is generated from the plurality of sets of collected information and wherein the map depicts snow maintenance vehicle physical locations of each of the plurality of snow maintenance vehicles and the at least one of weather and road conditions in an area of each snow maintenance vehicle.

4. The method of claim 3, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of a corresponding snow maintenance vehicle, and wherein each icon is associated with text information describing a vehicle state of the corresponding snow maintenance vehicle.

5. The method of claim 4, wherein the vehicle state of the corresponding snow maintenance vehicle comprises at least one of a snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal, and the at least one of weather and road conditions, input, on a manual basis, from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle.

6. The method of claim 4, wherein an appearance of the icon denotes a corresponding one of a plurality of different possible vehicle states of the corresponding snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

7. The method of claim 6, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

8. The method of claim 3, wherein the map provides a trace route for each of the plurality of snow maintenance vehicles.

9. The method of claim 1, wherein the instruction comprises one or more of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the map is provided over a cellular network, wherein the at least one of weather conditions and road conditions is weather conditions, and wherein the weather conditions comprise a plurality of temperature, humidity, wind speed, wind direction, wind chill, and precipitation type.

10. The method of claim 1, wherein the map is provided over a cellular network, wherein the at least one of weather conditions and road conditions is road conditions, and wherein the road conditions comprise one or more of icy, slushy, snow-packed, frosty, wet, and dry.

11. The method of claim 6, wherein the snow maintenance vehicle state comprises a plurality of a snow plow setting, a mixture of material being applied to a selected surface, and an amount of material being applied to the selected surface.

12. The method of claim 6, wherein the snow maintenance vehicle state comprises video images of the corresponding snow maintenance vehicle's exterior environment.

13. A method, comprising:

- (a) sending, over a wireless cellular network, from an Internet Protocol ("IP") address of a selected snow maintenance

21

nance vehicle, and to a server, a set of collected information, the set of collected information comprising a physical location of the selected snow maintenance vehicle, at least one of weather and road conditions in an area of the selected snow maintenance vehicle, and a unique identifier different from the IP address;

- (b) receiving, from the server and over the wireless cellular network, a map and an instruction, based on the set of collected information, for a snow maintenance vehicle and/or route;
- (c) displaying, to a user in the selected snow maintenance vehicle, the map; and
- (d) providing, to the fuser, the instruction, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

14. The method of claim 13, wherein the user is at least one of an operator of the selected snow maintenance vehicle and a dispatcher or representative of a governmental entity, business entity, or independent entity, wherein the instruction comprises one or more of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a Global Positioning System ("GPS")-based location, wherein the GPS-based location is received by a processor from a GPS module, and wherein the GPS-based location is a current and/or recorded snow maintenance vehicle physical location.

15. The method of claim 13, wherein the map is generated from the set of collected information, and wherein the map depicts snow maintenance vehicle physical locations of each of a plurality of snow maintenance vehicles, including the selected snow maintenance vehicle, and the at least one of weather and road conditions in an area of each snow maintenance vehicle.

16. The method of claim 13, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of the corresponding snow maintenance vehicle, and wherein each icon is associated with text information describing a vehicle state of the corresponding snow maintenance vehicle.

17. The method of claim 16, wherein the vehicle state of the corresponding snow maintenance vehicle comprises at least one of snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal, and the at least one of weather and road conditions, input and/or sensed, on a manual and/or automated basis, from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle.

18. The method of claim 16, wherein an appearance of the icon denotes a corresponding one of a plurality of different possible states of the corresponding snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

19. The method of claim 18, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

22

20. The method of claim 15, wherein the map provides a trace route for each of the plurality of snow maintenance vehicles.

21. The method of claim 13, wherein the instruction comprises one or more of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the map is provided by local and/or remote access, wherein the at least one of weather conditions and road conditions is weather conditions, and wherein the weather conditions comprise a plurality of temperature, humidity, wind speed, wind direction, wind chill, and precipitation type.

22. The method of claim 13, wherein the at least one of weather and road conditions is collected from the user on a manual basis, wherein the at least one of weather conditions and road conditions is road conditions, and wherein the road conditions comprise one or more of icy, slushy, snow-packed, frosty, wet, and dry.

23. The method of claim 18, wherein the snow maintenance vehicle state comprises a plurality of snow plow setting, mixture of material being applied to a selected surface, and amount of material being applied to the selected surface.

24. The method of claim 18, wherein the snow maintenance vehicle state comprises video images of the snow maintenance vehicle's exterior environment.

25. The method of claim 13, further comprising:

- (d) in response to engine shut off, delaying, by a DC voltage regulator and sequencer, termination of power to the processor to enable orderly initiation of processor shut down.

26. A method, comprising:

- (a) receiving, from a snow maintenance vehicle, information comprising a plurality of a current weather condition, a current road condition, a snow plow setting, a mixture of material being applied to a road surface, and an amount of material being applied to the road surface;
- (b) obtaining, by at least one processor, a physical location of the snow maintenance vehicle;
- (c) determining, by the at least one processor, that at least one of a received signal strength from a wireless network and a Quality of Service ("QoS") parameter is not acceptable;
- (d) buffering, by the at least one processor, the received information when the at least one of a received signal strength from a wireless network and a QoS parameter is determined not to be acceptable;
- (e) when the at least one of a received signal strength from a wireless network and a QoS parameter is determined to be acceptable, sending, by the at least one processor, from an Internet Protocol ("IP") address of the of the at least one processor, and over a wireless network, the received information and physical location to an electronic address associated with a remote server; and
- (f) receiving, by local and/or remote access, by a user, an instruction in response to the received information and physical location, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

27. The method of claim 26, wherein the received information is input, on a manual basis, from a snow maintenance vehicle, wherein the IP address is received by the at least one processor from a domain name server of a wireless network,

23

wherein the physical location is a set of location coordinates received from a Global Positioning System ("GPS") sensor, and wherein the determining step (c) comprises the sub-operations:

- (C1) forwarding, by the at least one processor, a query to an IP address of the domain name server and applying the following rules;
- (C2) when a response is received from the domain name server, determining that the at least one of a received signal strength from a wireless network and a QoS parameter is acceptable; and
- (C3) when no response is received from the domain name server, determining that the at least one of a received signal strength from a wireless network and a QoS parameter is not acceptable.

28. The method of claim 27, wherein the at least one of a received signal strength from a cellular wireless network and a QoS parameter is determined not to be acceptable and further comprising the sub-operations:

- (C4) determining, by the at least one processor, whether a communications initiation application is configured for a persistent connection and applying the following rules;
- (C5) when the communications initiation application is configured for a persistent connection, allowing, by the at least one processor, the communications initiation application to reestablish a connection with the server; and
- (C6) when the communications initiation application is not configured for a persistent connection, resetting logic and related parameters required for access to the wireless network to effect reestablishment of the connection with the server.

29. The method of claim 26, wherein the received information is based on information regarding vehicle state, input, on a manual basis, from a snow maintenance vehicle, and wherein the at least one processor sends, along with the received information, a unique identifier associated with the snow maintenance vehicle, the unique identifier being different from the at least one processor's IP address.

30. The method of claim 26, wherein a combination DC voltage regulator and sequencer provide key on/off functionality with delayed power-on to provide extended minimal voltage drain upon start and delayed power-off to provide extended session status with restart and/or orderly shut-down of the at least one processor and whatever functionality is then active.

31. The method of claim 26, wherein the user is at least one of an operator of a snow maintenance vehicle and/or dispatcher or representative of a governmental entity, business entity, or independent entity, wherein the instruction comprises one or more of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, and wherein the at least one processor is programmable, comprises an operating system, and provides interfaces for the transfer and/or receipt of information and instructions.

32. The method of claim 26, wherein the at least one processor comprises a connection manager to establish wireless connections and a connection monitor to monitor at least one network state parameter, the network state parameter being one or more of a signal strength over the wireless network, packet loss, jitter, and latency and, when the at least one network state parameter is determined not to be acceptable, to disconnect the connection.

33. The method of claim 26, wherein the instruction comprises one or more of a snow plow setting, a mixture of

24

materials being applied to a road surface, and an amount of materials being applied to the road surface and wherein the at least one processor comprises a filter operable to remove duplicated information and send only information that has changed since a prior transmission and/or information outside of set or calculated parameters.

34. A system, comprising:

at least one processor operable to:

- (a) receive, from a snow maintenance vehicle, information comprising a plurality of a current weather condition, a current road condition, a snow plow setting, a mixture of a material being applied to a road surface, and an amount of the material being applied to the road surface;
- (b) obtain a physical location of the snow maintenance vehicle;
- (c) determine that at least one of a received signal strength from a wireless network and a Quality of Service ("QoS") parameter is not acceptable;
- (d) buffer the received information when the at least one of a received signal strength from a wireless network and a QoS parameter is determined not to be acceptable;
- (e) when the at least one of a received signal strength from a wireless network and a QoS parameter is determined to be acceptable, send, from an Internet Protocol ("IP") address associated with the snow maintenance vehicle and over a wireless network, the received information and physical location to an electronic address associated with a remote server; and
- (f) receive, by local and/or remote access, by a user, an instruction in response to the received information and physical location, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

35. The system of claim 34, wherein the received information is input, on a manual basis, from a snow maintenance vehicle, wherein the IP address is received by the at least one processor from a domain name server of a wireless network, wherein the physical location is a set of location coordinates received from a Global Positioning System ("GPS") sensor, and wherein the determining operation (c) comprises the sub-operations:

- (B1) forwarding a query to an IP address of the domain name server and applying the following rules;
- (B2) when a response is received from the domain name server, determining that the at least one of a received signal strength from a wireless network and a QoS parameter is acceptable; and
- (B3) when no response is received from the domain name server, determining that the at least one of a received signal strength from a wireless network and a QoS parameter is not acceptable.

36. The system of claim 35, wherein the at least one of a received signal strength from a wireless network and a QoS parameter is determined not to be acceptable and further comprising the sub-operations:

- (B4) determining whether a communications initiation application is configured for a persistent connection and applying the following rules;
- (B5) when the communications initiation application is configured for a persistent connection, allowing the communications initiation application to reestablish a connection with the server; and

25

(B6) when the communications initiation application is not configured for a persistent connection, resetting logic and related parameters required for access to the wireless network to effect reestablishment of the connection with the server.

37. The vehicle of claim 34, wherein the received information is based on information regarding vehicle state, input, on a manual basis, from a snow maintenance vehicle, and wherein the at least one processor sends, along with the received information, a unique identifier associated with the snow maintenance vehicle, the unique identifier being different from the at least one processor's IP address.

38. The vehicle of claim 34, wherein a combination DC voltage regulator and sequencer provides key on/off functionality with delayed power-on to provide extended minimal voltage drain upon start and delayed power-off to provide extended session status with restart and/or orderly shut-down of the at least one processor and whatever functionality is then active.

39. The vehicle of claim 34, wherein the user is at least one of an operator of a snow maintenance vehicle and a dispatcher or representative of a governmental entity, business entity, or independent entity, wherein the instruction comprises one or more of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, and wherein the at least one processor is programmable, comprises an operating system, and provides interfaces for the transfer and/or receipt of information and instructions.

40. The vehicle of claim 34, wherein the at least one processor comprises a connection manager to establish wireless connections and a connection monitor to monitor at least one network state parameter, the network state parameter being one or more of a signal strength over the wireless network, packet loss, jitter, and latency and, when the at least one network state parameter is determined not to be acceptable, to disconnect the connection.

41. The vehicle of claim 34, wherein the instruction comprises one or more of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface and wherein the at least one processor comprises a filter operable to remove duplicated information and send only information that has changed since a prior transmission and/or information outside of set or calculated parameters.

42. A method, comprising:

- (a) while a snow maintenance vehicle is in operation, periodically sending, over a wireless network, from an Internet Protocol ("IP") address of a processor associated with the snow maintenance vehicle, and to a server, a set of collected information, the set of collected information comprising a physical location of the snow maintenance vehicle, at least one of weather and road conditions in an area of the snow maintenance vehicle, and a unique identifier different from the IP address; and
- (b) in response to engine shut off of the snow maintenance vehicle, delaying, by a DC voltage regulator and sequencer, termination of power to the processor to enable orderly initiation of processor shut down.

43. The method of claim 42, further comprising:

- (b) receiving, by local and/or remote access and from the server, a map and an instruction, based on the set of collected information, for a snow maintenance vehicle and/or route;

26

(c) displaying, to a user, the map; and

(d) providing, to the user, the instruction, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

44. A system, comprising:

a processor operable to determine a physical location of the snow maintenance vehicle, collect, by a sensor and/or user interface, from a snow maintenance vehicle, information comprising a plurality of a current weather condition, a current road condition, a snow plow setting, a mixture of a material being applied to a road surface, and an amount of the material being applied to the road surface, and provide, to a remote server, the collected information comprising the physical location and the plurality of a current weather condition, a current road condition, a snow plow setting, a mixture of a material being applied to a road surface, and an amount of the material being applied to the road surface; and

a combination DC voltage regulator and sequencer operable to provide key on/off functionality with delayed power-on to provide extended minimal voltage drain upon start and delayed power-off to provide extended session status with restart and/or orderly shut-down of the processor and whatever processor functionality is then active.

45. The system of claim 44, wherein the processor is further operable to:

determine that at least one of a received signal strength from a wireless network and a Quality of Service ("QoS") parameter is not acceptable;

buffer the collected information when the at least one of a received signal strength from a wireless network and a QoS parameter is not acceptable;

when the at least one of a received signal strength from a wireless network and a QoS parameter is acceptable, send, from an Internet Protocol ("IP") address of the processor and over a wireless network, the collected information to an electronic address associated with the remote server; and

receive, by local and/or remote access, by the operator of the snow maintenance vehicle and/or other user, an instruction to the snow maintenance vehicle operator and/or route, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

46. A system, comprising:

at least one processor operable to:

- (a) send, over a wireless cellular network, from an Internet Protocol ("IP") address of a selected snow maintenance vehicle, and to a server, a set of collected information, the set of collected information comprising a physical location of the selected snow maintenance vehicle, at least one of weather and road conditions in an area of the selected snow maintenance vehicle, and a unique identifier different from the IP address;

27

- (b) receive, from the server and over the wireless cellular network, a map and an instruction, based on the set of collected information, for a snow maintenance vehicle and/or route;
- (c) display, to a user of the snow maintenance vehicle, the map; and
- (d) provide, to the user, the instruction, the instruction comprising one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, an alarm based on a difference in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

47. The system of claim 46, wherein the user is at least one of an operator of the corresponding snow maintenance vehicle and dispatcher or representative of a governmental entity, business entity, or independent entity, and wherein the instruction comprises one or more of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a Global Positioning System ("GPS")-based location, wherein the GPS-based location is received by the at least one processor from a GPS module, and wherein the GPS-based location is a current and/or recorded snow maintenance vehicle physical location.

48. The system of claim 46, wherein the map is generated from the set of collected information and wherein the map depicts snow maintenance vehicle physical locations of each of a plurality of snow maintenance vehicles, including the corresponding snow maintenance vehicle, and the at least one of weather and road conditions in an area of each snow maintenance vehicle.

49. The system of claim 46, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of a respective snow maintenance vehicle, and wherein each icon is associated with text information describing a vehicle state of the respective snow maintenance vehicle.

50. The system of claim 49, wherein the vehicle state of the respective snow maintenance vehicle comprises at least one of snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle and wherein an appearance of the icon denotes a corresponding one of a plurality of different possible vehicle states of the respective snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

51. The system of claim 50, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

52. The system of claim 49, wherein the map provides a trace route for each of the plurality of snow maintenance vehicles.

53. The system of claim 46, wherein the instruction comprises one or more of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the at least one of weather in an area of the corresponding snow maintenance vehicle, road conditions in an area of the corre-

28

sponding snow maintenance vehicle, and a vehicle state of the corresponding snow maintenance vehicle is weather conditions, and wherein the weather conditions comprise a plurality of temperature, humidity, wind speed, wind direction, wind chill, and precipitation type.

54. The system of claim 46, wherein the at least one of weather and road conditions is collected from the user on a manual basis, wherein the at least one of weather and road conditions in an area of the corresponding snow maintenance vehicle is road conditions, and wherein the road conditions comprise one or more of icy, slushy, snow-packed, frosty, wet, and dry.

55. The system of claim 50, wherein the snow maintenance vehicle state comprises a plurality of snow plow setting, mixture of material being applied to a selected surface, and amount of material being applied to the selected surface.

56. The system of claim 50, wherein the snow maintenance vehicle state comprises video images of the snow maintenance vehicle's exterior environment and further comprising:

- a DC voltage regulator and sequencer to delay, in response to engine shut off, termination of power to the at least one processor to enable orderly initiation of at least one processor shut down.

57. The system of claim 46, wherein the at least one processor is in the corresponding snow maintenance vehicle and further comprising a user interface to collect from the user and send, from the operator, the set of collected information, and to display, to the operator, the map, and provide, to the operator, the operator and/or route instruction.

58. A system, comprising:

- (a) a server operable to: (i) communicate, over a wireless network, with a plurality of snow maintenance vehicles operated by a plurality of different independent entities; (ii) obtain, for each snow maintenance vehicle, information comprising the current snow maintenance vehicle physical location and at least one of a weather condition and a road condition in the vicinity of the snow maintenance vehicle, (iii) generate at least one of (A) an instruction for a respective snow maintenance vehicle and/or route, comprising one or more of a dispatch command, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface and (B) an alarm to at least one of a user associated with the respective snow maintenance vehicle and/or route and an automated component in the respective snow maintenance vehicle, (iv) generate, for each independent entity, a map, and (v) provide, to a user associated with such entity, the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm and a selected map for display, the selected map being for the independent entity associated with the respective snow maintenance vehicle and/or route; and

- (b) at least one database operable to store, for each snow maintenance vehicle and for each independent entity, respective information collected by the server.

59. The system of claim 58, wherein the user is at least one of an operator of a snow maintenance vehicle and a dispatcher or representative of a governmental entity, business entity, company, or independent entity, and wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm and the selected map is provided to the user by local and/or remote access.

60. The system of claim 58, wherein the obtained information is input, on a manual basis, from a respective snow maintenance vehicle, and wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or

29

or route and (B) an alarm and the selected map is provided to at least one of a user and an automated component of the selected snow maintenance vehicle by a wireless network.

61. The system of claim 58, wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm is an alarm, wherein the alarm is at least one of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a set of Global Positioning System ("GPS") coordinates, wherein each snow maintenance vehicle comprises a respective GPS location unit to provide a current snow maintenance vehicle location, and wherein the current snow maintenance vehicle physical location is sent, by each snow maintenance vehicle, to the server to be used in generation of the map.

62. The system of claim 58, wherein the server generates, using obtained information, the map, for a selected independent entity, showing an icon associated with each of the snow maintenance vehicles currently in operation for that selected independent entity, with each icon indicating a current physical location and at least one of a status of the corresponding snow maintenance vehicle, road conditions in the vicinity of the snow maintenance vehicle, and weather conditions in the vicinity of the snow maintenance vehicle.

63. The system of claim 58, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of the corresponding snow maintenance vehicle, and wherein each icon is associated with text information describing a vehicle state of the corresponding snow maintenance vehicle.

64. The system of claim 61, wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm is an instruction for the respective snow maintenance vehicle and/or route, wherein the instruction is at least one of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the vehicle state of the corresponding snow maintenance vehicle comprises at least one of snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle.

65. The system of claim 63, wherein an appearance of the icon denotes a corresponding one of a plurality of different possible vehicle states of the corresponding snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

66. The system of claim 63, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

67. The system of claim 58, wherein the map provides a trace route for each of a set of the plurality of snow maintenance vehicles.

68. The system of claim 62, wherein the plurality of current weather conditions, road conditions, snow plow setting, mixture of material being applied to a road surface, and amount of material being applied to the road surface is collected on a manual basis, by a user interface, from a snow maintenance vehicle, and wherein the collected information comprises a plurality of raining, snowing, blowing snow, foggy, clear, overcast, icy road, slushy road, snow-packed road, frosty road, wet road, dry road, snow maintenance vehicle position, snow plow orientation, mixture of material being applied to the road, and amount of material being applied to the road.

30

69. A method, comprising:

receiving, by a server over a wireless network, information associated with a plurality of snow maintenance vehicles operated by a plurality of different independent entities, the information comprising, for each snow maintenance vehicle, the current snow maintenance vehicle physical location and at least one of a weather condition and a road condition in the vicinity of the snow maintenance vehicle;

generating at least one of (A) an instruction, for a respective snow maintenance vehicle and/or route, comprising one or more of a dispatch command, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface and (B) an alarm to at least one of a user associated with the respective snow maintenance vehicle and/or route and an automated component in the respective snow maintenance vehicle;

generating, for each independent entity, a map;

providing, to a user associated with such entity, the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm and a selected map for display, the selected map being for the independent entity associated with the respective snow maintenance vehicle; and

storing, in at least one database, for each snow maintenance vehicle, and for each independent entity, respective information collected by the server.

70. The method of claim 69, wherein the user is at least one of an operator of a snow maintenance vehicle and a dispatcher or representative of a governmental entity, business entity, or independent entity, and wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm and the selected map is provided to the user by local and/or remote access.

71. The method of claim 69, wherein the received information is input, on a manual basis, from a snow maintenance vehicle, and wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm and the selected map is provided to at least one of a user and an automated component of the selected snow maintenance vehicle by a wireless network.

72. The method of claim 69, wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm is an alarm, wherein the alarm is at least one of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a set of Global Positioning System ("GPS") coordinates, wherein each snow maintenance vehicle comprises a respective GPS location unit to provide a current snow maintenance vehicle location, and wherein the current snow maintenance vehicle physical location is sent, by each snow maintenance vehicle, to the server to be used in generation of the map.

73. The method of claim 69, wherein the server generates, using obtained information, the map, for a selected independent entity, showing an icon associated with each of the snow maintenance vehicles currently in operation for that selected independent entity, with each icon indicating a current physical location and at least one of a status of the corresponding snow maintenance vehicle, road conditions in the vicinity of the snow maintenance vehicle, and weather conditions in the vicinity of the snow maintenance vehicle.

74. The method of claim 69, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of the corresponding snow maintenance vehicle, and

31

wherein each icon is associated with text information describing a vehicle state of the corresponding snow maintenance vehicle.

75. The method of claim 72, wherein the at least one of (A) an instruction for the respective snow maintenance vehicle and/or route and (B) an alarm is an instruction for the respective snow maintenance vehicle and/or route, wherein the snow maintenance vehicle operator instruction is at least one of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the vehicle state of the corresponding snow maintenance vehicle comprises at least one of snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle.

76. The method of claim 74, wherein an appearance of the icon denotes a corresponding one of a plurality of different possible vehicle states of the corresponding snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

77. The method of claim 74, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

78. The method of claim 69, wherein the map provides a trace route for each of a set of the plurality of snow maintenance vehicles.

79. The method of claim 73, wherein the plurality of current weather conditions, road conditions, snow plow setting, mixture of material being applied to a road surface, and amount of material being applied to the road surface is collected on a manual basis, by a user interface, from a snow maintenance vehicle, and wherein the collected information comprises a plurality of raining, snowing, blowing snow, foggy, clear, overcast, icy road, slushy road, snow-packed road, frosty road, wet road, dry road, snow maintenance vehicle position, snow plow orientation, mixture of material being applied to the road, and amount of material being applied to the road.

80. A system, comprising:
a server operable to:

- (a) receive over a wireless network, from a plurality of snow maintenance vehicles, a plurality of sets of collected information, each of the collected sets of information comprising a respective snow maintenance vehicle physical location and at least one of weather and road conditions in an area of the respective snow maintenance vehicle;
- (b) process the received collected information to (i) provide a map associated with a physical location of a selected snow maintenance vehicle and (ii) determine an instruction for the selected snow maintenance vehicle and/or route; and
- (c) provide, over the wireless network, the map and an instruction to a user in the selected snow maintenance vehicle, wherein the map is visually displayed to the user and wherein the instruction comprises one or more of a dispatch command, an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface.

81. The system of claim 80, wherein the user is at least one of an operator of the selected snow maintenance vehicle and a dispatcher or representative of a governmental entity, business entity, or independent entity, and wherein the instruction

32

comprises one or more of an alarm based on a temporal trend in weather conditions, an alarm based on a difference in weather conditions, an alarm based on a temporal trend in road conditions, and an alarm based on a difference in road conditions, wherein the physical location is a Global Positioning System ("GPS")-based location of the selected snow maintenance vehicle, wherein the GPS-based location is received by the processor from a GPS module, wherein the GPS-based location is a current and/or recorded snow maintenance vehicle physical location, and wherein each of the sets of collected information includes a unique identifier associated with the respective processor, the unique identifier being different from a processor's IP address.

82. The system of claim 80, wherein the map is generated from the plurality of sets of collected information, and wherein the map depicts snow maintenance vehicle physical locations of each of the plurality of snow maintenance vehicles and the at least one of weather and road conditions in an area of each snow maintenance vehicle.

83. The system of claim 82, wherein the map comprises an icon for each of the plurality of snow maintenance vehicles, a respective map location of each icon depicting a physical location of a corresponding snow maintenance vehicle, and wherein each icon is associated with text information describing a vehicle state of the corresponding snow maintenance vehicle.

84. The system of claim 83, wherein the vehicle state of the corresponding snow maintenance vehicle comprises at least one of a snow maintenance vehicle identifier, direction of snow maintenance vehicle travel, snow maintenance vehicle speed, status of a GPS signal, and road and/or weather information, input, on a manual basis, from the snow maintenance vehicle, and timestamp of last data update for the snow maintenance vehicle.

85. The system of claim 83, wherein an appearance of the icon denotes a corresponding one of a plurality of different possible vehicle states of the corresponding snow maintenance vehicle with differing icon appearances corresponding to differing snow maintenance vehicle states.

86. The system of claim 85, wherein the appearance is color and wherein the color indicates that the snow maintenance vehicle is one of active, inactive, and out-of-wireless range.

87. The system of claim 82, wherein the map provides a trace route for each of the plurality of snow maintenance vehicles.

88. The system of claim 80, wherein the instruction comprises one or more of a snow plow setting, a mixture of materials being applied to a road surface, and an amount of materials being applied to the road surface, wherein the map is provided, over a cellular network, wherein the at least one of weather conditions and road conditions is weather conditions, and wherein the weather conditions comprise a plurality of temperature, humidity, wind speed, wind direction, wind chill, and precipitation type.

89. The system of claim 80, wherein the map is provided, over a cellular network, wherein the at least one of weather conditions and road conditions is road conditions, and wherein the road conditions comprise one or more of icy, slushy, snow-packed, frosty, wet, and dry.

90. The system of claim 85, wherein the snow maintenance vehicle state comprises a plurality of a snow plow setting, a mixture of material being applied to a selected surface, and an amount of material being applied to the selected surface.

91. The system of claim 85, wherein the snow maintenance vehicle state comprises video images of the corresponding snow maintenance vehicle's exterior environment.
